Summary: comments on ST

+++++++Line eaters do not exist any more, do they?++++++++

Just a few comments about the ST.

In answer to question about power supply compatibility with Europe, the story Atari people told me is that since the disk drive and computer run on DC power supplies, there is no problem. You just buy the European power supply (ie device for converting AC to DC) in Europe. I was told they might have a few European power supplies lying around in the US, and that a dealer could get hold of them, probably. The SM124 runs at 70 Hz, a fact that is well documented in magazines etc. It would actually be a good idea to have some sort of listing of all the articles on the ST written in magazines.

I for one would like to know exactly which issue of BYTE had the technical article on the ST. A lot of questions asked here are answered in the articles I read before buying an ST. Now the monitor actually plugs directly into the wall. So I am not quite so clear as to how to adapt the monitor to 50 Hz Power. But at least the sync is not derived from the 60 Hz waveform, which is cause for some optimism in this regard.

The delightful screen quality that results from a combination of 70 Hz scanning + non-reflective screen + etc. etc. is one of the pleasures of the ST. Does anyone know how to spread the dots over the full screen???

On the subject of ST/Amiga comparisons, it certainly is noce to get new information, especially when one is trying to make a decision on a purchase, but questions like which one has the best screen, software etc. are unanswerable. Questions about comparisons should be very specific, and the questioner should invest in copies of the dozen or so articles that have appeared lately.

Incidentally, I'm using my ST at the moment in VT52 Emulation mode over a phone line to a VAX to write this note. The VT52 Em does 99% of things just as the vi editor on UNIX wants it to. (Sometimes it makes an error

counting lines and positions the cursor on the screen one line above where it is in the file.) But I must say that the copy of STTALK I have makes a complete and utter mess of the very same commands from vi.

STTALK is perfect at communicating files via XMODEM, and the CAPTURE mode also works perfectly. But instructions from vi just push the cursor to the right of the screen, from which it never escapes. Hence I have had to leave STTALK for the VT52 emulator to write this note.

The VT52 Emulator has just made the error I mentioned. I escaped from insert mode to replace two erroneous characters. And when I went back to inserting, the cursor appeared one line above where it was (hopefully) in the file. I'll have to check if this is truly so.

Has anybody else found these problems, and if so, do you know the solution(s)?

Another problem is line noise at 1200 baud. Every 15 characters or so at 1200 baud, the VAX seems to receive a ^C from me. (With roughly Poisson distribution of arrival.) So I suffer with 300 baud. This makes reading superfluous info/questions painful.

The version of STTALK I use is V1.0. I also have version 0.95. Has a version later than 1.0 yet appeared?

So long,

Alan Kennington.

Yes BUT the bus speed of the Amiga is 14.4 MHz as opposed to the
ST which is 8MHz. The Amiga's 68000 runs at 7.2 MHz while the
Co-processors use the other 7.2 MHz.

The problem isn't necessarily the price but the fact that although
they advertise the system unbundled they won't sell it to you in
pieces. I haven't bought any computer equipment but I have had similar
experiences with photo equipment. Since the store cited was
Executive Photo the connection is clear. It's a trick to get
you in the door. It's not illegal since it isn't technically
false advertising; they just aren't giving you the entire story
up front. Old adage: If the seems too good to be true, it probably is.

I cannot answers your other concerns but since I have the Microsoft II software, I can help you with it. First of all the cartridge is full, therefore Atari put some additional commands on the disk (such as TROFF and TRON, etc.) however, you can use the cartrige by itself. There was an earlier all disk version that was not as complete as the cartridge version.

As far as putting the cartridge on disk, there is some hardware out to do just that, but I do not know what it is called. I suppose that you could do this, but to what advantage, I do not know. I personally prefer cartridges -- the computer is set up to use cartridges anyway, there is memory allocated for the carts.

I hope this helps you, maybe some other Atarians can help you out. By the way, another good BASIC language is BASIC XL or BASIC XE (depending on whether you are using an 800XL or an 130XE. As I understand it you can use BASIC XE on an 800XL -- this is one that I have not purchased yet. ACtion! is also good, it is a cross between C and Pascal. Again I do not own it, so others could probably answer your questions better on these two language carts.

I agree that the STTALK is totally useless as terminal emulator. But
you can still try, remembering that sttalk give you a 21 line vt52
instead of the usual 25. So the TERMCAP entry has to be appro.
adjusted (li#21).
    I have not encountered the problem with the cursor jumping
to the wrong line. I normally use Gnuemacs, not Vi, but I don't
think that should matter. It sounds like a character or so is getting
dropped. So you may try fine tuning the padding in your TERMCAP entry.
I fine tuned my entry so that I get no Xon/Xoff when I hit a ^L in the
editor to refresh a screen full (Xon/offs play havoc with emacs). I
usually use the St uver a 2400 Baud modem with a simple terminal
emulator that uses Xbios calls to do output, so the Bios takes care
of the Vt52 emulation. I also use the St over a 9600 Baud line, with
no problem (ie. after tuning my TERMCAP entry). I have also used
the emulator in the 50 Line mode after adjusting the TERMCAP entry
(li#50) with no problems.
    V1.1 id Sttalk is avail. by sending your origonal disk and $2
to them . I received mine a couple of days back. It still has the
brain damaged bars, but a lot if the bugs have been cleared, added
a coouple of feature, like remembering Baud rates with the Dial
Entries, Dial prefixes, Entry A's Baud Rate is the Baud rate it comes
up in, etc. etc.

&&&&&&&&&&&&& le mangeur des lignes? il n'existe plus! &&&&&&&&&&

The sequence of arguments about relative use of the bus by ST and Amiga has previously appeared at least once, and I think perhaps twice. Last time we were told about how, if necessary, the other chips can steal time when they're in a tight spot. For those Atari users who have only short-term memory, perhaps someone at Amiga should tell us all again about these fascinating phenomena which occur in their wondrous machine.

Actually I have myself made use of such discussions to settle on the ST. But I think discussion should go around in a circle only twice a month at most, rather than the present 4 times.

Felices Pascuas,
Alan Kennington.

1) Termcap entry for 520ST emulating a vt52:
    The following termcap entry works fine with our 4.2bsd system on
    a VAX 11/780. (I have a B&W high res monitor and this termcap
    has been used at 1200 baud only.)

```
at|vt52at|520st emulating vt52:\
     :co#80:li#25:cr=^M:nl=^J:le=^H:ta=^I:bl=^G:bs:pt:\
     :is=\Ev\Ee:am:cd=\EJ:ce=\EK:cl=\EE:\
     :up=\EA:do=\EB:nd=\EC:sr=\EI:\
     :al=\EL:dl=\EM:so=\Ep:se=\Eq:\
     :cm=\EY%+ %+ :
```

    it solves many of the mysterious problems experienced while
    using the "standard" vt52 termcap (incorrectly positioned cursor etc.)
2) ST BASIC: READING MOUSE POSITION
    The example given for the command GEMSYS (on page C-57) in the
    BASIC manual does just this.
3) ST BASIC: WAVE COMMAND
    The ENABLE parameter has its bits turned ON by 1's and OFF by 0's.
    The manual says exactly the opposite.
                                                        Dinesh

In <382@pedsgd.UUCP>, Bob Halloran <bobh@pedsgd.UUCP> ventures:

> "Granted, the graphics chips relieve the [Amiga's] 68000 from
> dealing with the display, as it must in the Mac, but the 68000
> and the various co-processors must still contend for access to
> memory. YES, I/O can proceed independently, etc., but only ONE
> of the processors can use memory at a time. This HAS to impact
> the throughput of the 68000."

This turns out not to be the case. First, the Amiga's coprocessors can *only* access the first 512k of RAM. Any additional RAM resides on a completely separate bus to which only the 68000 has access. The loader allows a program developer to specify that those program segments containing graphics structures should reside in the shared RAM, and the remainder of the program in "fast" RAM, if available.

Second, the shared bus is run at twice the CPU speed, and the CPU and coprocessors use alternate bus cycles. Thus, under "normal" conditions the CPU sees no bus contention whatsoever. Only when the coprocessor bus cycles are inadequate for a particular task do the coprocessors begin to preempt the CPU's bus cycles. Most commonly, this happens whenever a 640-pixel-wide display with more than 3 (I think) bit planes must be displayed. Default text windows use the 640-wide mode with two bit planes, and so do not slow the CPU.

N.B. I own neither of the machines being compared. Much of the above information comes from INFO-AMIGA postings by Amiga technical personnel, and any inaccuracies therein are no doubt due to my faulty recollection of those messages. I welcome corrections.

I would still like to know why the Amiga even with a 68020 and fast memory still is *significantly* slower than the ST. Is their a hardware type out their who can look at the memory cycles and see why the current claims of "no cpu slowing due to graphics chips" seems to not be proved by the real world. If I had one I would do it myself. If possible could a Amiga hardware engineer explain this disparity? It seems very strange. P.S. I know that the clock is slightly slower.

I feel the continuous talk of whether the Atari ST is better than the Amiga or vice versa tedious and boring. No one learning anything from it.

So, I propose a New Year Resolution.

From Jan 1st - all discussion on this topic should finish.

Can we have a little bit more of

I have found that....

How do I.....

There is a bug in....

I just found out how to copy files from one disk to another using a single disk drive. The reason I was so late in finding out about this is, I think, that the owner's manual does not mention how to (so I was left with the impression that I had to wait for the developer kit to get the utilities to copy files as above). I am sure that many of you with Mac experience knew how to copy before you even opened your ST package. But I did not have any Mac time before I opened mine and I think many others are in the same boat. This message is for that group.

To copy a file from disk A to disk B using one disk drive, open disk A and select and drag the icon representing the file to be copied to the disk B icon. Dialog boxes will direct the copying process from there. You will be asked to insert disk A then B then A and so on depending on how many files you want copied in much the same way that you are asked to switch disks during an entire disk copy.

I am sorry for boring many of you with this message but I am SURE that some people will benefit from it. My life has been made a fair bit simpler now that I know about this. Thanks to Alan Pratt for letting me in on this.

One more point: If anyone has suddenly found out how to do something he or she has been trying to do for some time but did not know how to do because the manual did not mention it or explained it poorly I think a fair number of people might be interested in hearing about it.

WHy would they want to put AT&T V7 on the 32 bit machine. There is no
excuse for anything less than 4.3BSD + a nice window manager considering
the hardware they are putting it on. I personally hope that they will
provide a higher res color bitmap alternative than the ST otherwise
they have no chance to break into the low-cost workstation marketplace.
There are certain minimum levels of functionality that I hope atari is
aware of or they will find themselves in limbo like the amiga, which is
too expensive for a home machine and not good enough for any serious
cad/cam work.

We called them (their 800 # has been dis-connected) and asked about the price of the 520st. We got the same story at Bob Halloran, however, we have one additional comment to add: the package with the color monitor is $899, a far cry from $369. In case anyone else wants to give them a call, their number is 212-947-5290. It might not be a bad idea if you folks in the N.Y. area give these "people" a call and express your dismay at their price (and false advertising). They might have second thoughts the next time.

 Now that it appears unlikely that a real UNIX will apprear for the ST,
what about UNIX subsets? A few of these appeared on the IBM side of the
market (aside from 1 or 2 real UNIX implementations such as XENIX) and
have some supporters. Typically multitasking abilities are eliminated
or greatly reduced but at least the more common commands are the same
and, due to the great simplification, it isn't pure folly to run some
of them on a floppy system.

 Understand I'm not volunteering for this sort of thing (The ATs' XENIX
bugs keep me plenty busy) but am curious if 1) There is a demand and 2)
anyone is working on such a beast.

The Atari Insight column of January Compute! magazine supports holding
on to your old 8-bit "clunker" rather than taking the leap to the 520ST,
at least for the present. The software available for the 520 still
can't match the variety of 8-bit stuff that is lying around;
furthermore, who needs 16 bits to write letters and manage a recipe data
base?

Hi all

Here in Israel, I have yet to see the ST model computers come out. We
recently bought an Atari 800XL and it is running fine for us. However,
the software prices in Israel are atrocious, as are the books. For
instance, if you are interested in buying one of COMPUTE!'s tutorials,
be prepared for a price of around 27 dollars for it. Is this reasonable?
As for MICROSOFT BASIC II, a must I think for anyone who wants to use
really SERIOUS basic, it runs for around 100 bucks here, with the cartridge
and diskette and book. One place had the cartridge ripped off from the
box and I checked to see if they would sell me the book, but they only
agreed to sell diskette and book, for around 50 dollars. I can't afford
this stuff. There are serious problems though. We did buy one book

on Microsoft Basic (geared more towards the TRS-80 computers, but essentially the same basic). The problem is ---> what about Atari's special commands. How do I open to write on the disk when I'm in MICROSOFT BASIC. How about Graphics? Does MICROSOFT BASIC handle graphics on the atari, or do I throw out a really neat version of basic just so i can use the graphics and colors. Is this ONLY covered in the book that comes with Atari MICROSOFT BASIC II?

My request is that if anyone has this kind of info and is willing to answer some questions...we need HELP! And if anyone has help info on these subjects, including my next set of questions, on the computer that can be sent to me, could you? It would be IMMENSELY appreciated.

Okay, now for the next morsel. We got visicalc running, and again, no documentation. HELP! If anyone has even a general guide to commands or some hints for using visicalc, HELP!

Isn't this the greatest S.O.S. you guys have ever gotten??

Next is there anyway to transfer software over this net. For instance, even if compiled assembler programs can't be sent, can assembler programs be sent and then compiled after being written onto the disk?

And finally, WHERE ARE ALL THE OWNERS OF 800XL's??????? come on guys... has the ST killed off XL completely?

Thanks.

Randy Magruder

I have not yet seen any discussion of the relative merits of Amiga and ST software here. This is suprising, considering that software is one department where the ST takes a good drubbing from the Amiga. The ST's O.S. is derived, I think, from CPM68k. I never heard a nice word about that O.S. The Amiga's O.S. is derived from Tripos (sp?), which is a very nice, clean multi-tasking system.

Let's see some flamage here!

I also saw this in one magazine. Other magazines have it like this:

         ATARI 520ST .... COMMODORE AMIGA
colors: 512   4096
color output: yes   yes

It looks like they just screwed up in some publications.

As for misleading advetising, did you know the Amiga has a meg of ram?
That was my first reaction to the ad that says the Amiga has twice as
much memory as a Macintosh. At least Atari tells you what exactly they
are comparing against.

This was supposed to go to usenet@ucbvax.berkeley.edu but was not deliverable.

Anybody know how to change the baud rate on a casette save/load? My recorder
seems to have a problem running at constant speed and I thought if I could
drop down from the standard 600 baud to 300 (or even 150), I might be able
to get it to work again. I already tried changing the audio frequency
generators to a lower baud rate (successfully) but as soon as I type
'CSAVE' (or 'LIST "C:"), they go right back to 600 baud again. Is there some
peek address that can be poked to a lower baud rate that the cassette routines
use?

Wrongo. ** PLEASE IF YOU ARE GOING TO POST SOMETHING, BE SURE OF YOUR FACTS
OR WARN US YOU ARE SPECULATING **

The ST interleaves processor with coprocessor bus accesses just like the Amiga
does. So you might have said:

The bus speed of the Amiga is 14.4 MHz as opposed to the ST which is 16 MHz.
The Amiga's 68000 runs at 7.2 MHz while the coprocessors use the other
7.2 MHz, compared with the ST's 68000 which runs at 8 MHz while the
coprocessors use the other 8 MHz.

(But saying a bus runs at X MHz means nothing. You might want to say that
 the Amiga can transfer 16 bits of information in 280 ns, while the ST can
 transfer 16 bits of information in 250 ns. This doesn't mean the ST is
 better than the Amiga, either, since (I am not sure) the Amiga might be
 able to do a graphics transfer in the "chip memory" at the same time as a
 processor transfer in the "expansion memory", giving higher throughput.
 But only for Amiga owners with expansion memory).

Boo hoo. I paid $800 US for a fast computer with 1 meg of memory, 720K disk,
and lovely 640 x 400 non interlaced monitor. Boo hoo hoo.

{traditional offering to line-eater goes here}

In a reply to [yet another] posting comparing the ST and Amiga, the following appears:

>Yes BUT the bus speed of the Amiga is 14.4 MHz as opposed to the
>ST which is 8MHz. The Amiga's 68000 runs at 7.2 MHz while the
>Co-processors use the other 7.2 MHz.
>
>Mike Gingell   ...decvax!mcnc!ecsvax!mjg

Mr. Gingell probably represents the Amiga side of the "debate" accurately, but not the Atari ST side. At the risk of fanning more ST vs Amiga debate, I would like to correct the information above. The Atari ST has a separate bus for the processor which does indeed run at 8 MHz; but the main memory bus, used to service the graphics chip and memory management unit runs at 16 MHz. Further, the graphics chip runs at 32 MHz (I don't know why, it's in my schematics -- you did get schematics with your development kit, didn't you?). The Atari uses the same sort of time multiplexing that the Amiga does, but has only one type of memory which can be expanded to 4 MByte in two banks (using 32 1Meg RAMs).

Now I would like to ask that both sides of this mock debate cool down a bit and move on to more meaningful issues. Most computer owners (and also those who have made up their minds) would rather fight than admit the other guy's is better. I admit that for some applications the other guy's (Amiga) is better, just not for my applications. Now that should settle things, let's move on or move this discussion to net.flame (or /dev/null) where it belongs.

Lee Mendoza (The Aerospace Corporation, ARPAnet: mendoza@aerospace.arpa)

I'm posting this for a friend of mine, who would like to sell the following:

$500 for all this:

Atari 800 w/48 kilobytes RAM
1050 drive
1000e modem (300 baud protocol)
1027 printer
cassette recorder
SAM voice disk
50 games
BASIC
Atariwriter w/ manual
lot of other stuff
includes documentation for computer, BASIC, disk drive, printer, and modem, most of the games.

Please phone Jason at 1-201-379-5841 (Jason's about 14 years old.)
It'd be nice if you lived around Jersey, but not necessary.

Thanks for your time.

Does anyone know of any programs that make use of the MIDI capabilities of the Atari ST? I am just now getting interested in synthesis in general, and would like to use it as a sequencer for all the midi keyboards that I don't yet own. :-)

Anyone working on this?

Aloha

Several Points of Comparison in the Amiga vs ST Debate

>1) The official Atari price of the ST system that has received so much
> praise in this mailing list is actually $1798 (799 for the monochrome
>version, plus 999 for the color version). Each version will do things
that the other will not, and it is usually the composite of these
>functions that is represented as the overall capability of the ST.
>Atari has not to my knowledge offered to sell the monitors other than
>as part of a package deal. (I personally tend to favor the monochrome
>version - it seems to be best for the things the ST does the best.)

shear nonsense. if i desired a color atari monitor it could be had.
the current problem is the high demand for STs.
some dealers have also unbundled the atari package.

>2)
.....
>   With the ST, there is a choice between optimized color graphics
>and optimized text that must be made at purchase time. The standard
>Amiga monitor is reported to do a good job for both graphics and text,
>and other monitors (including cheap monochrome monitors) can be used

???this is pretty interesting given the observations on the net regarding
Atari versus Commodore monitors. My own observation is that the showfloor
mode for the Amiga really doesn't do the machine justice. Text on BOTH
machines with their respective color monitors is no worse/better.
And yes you are probably right Amiga would probably be better off with
a cheap monochrome monitor for text.

>3) It is to be expected that one would find a point in time in which
>there is more software commercially available for the ST than for the
>Amiga, since the ST is several months ahead in its development and
>marketing.

I agree with this. Tho' i should mention that at
a local Atari dealer in Seattle, a fellow who had bought an Amiga
traded it in for an 520ST. A straight trade. The store is using it
as a point of comparison for shoppers. The guy claimed that he could
get absolutely no software for it. Naturally the dealer was more
than willing to take it off his hands.

>4) Commodore/Amiga has been fairly open and honest about the internal
>structure and functioning of their machine, while by comparison
>Atari has been relatively secretive (specific examples furnished upon
>request).
more nonsense.
From all the various postings in this net group...Commodore hasn't
exactly been a source of openness. Re: Developer's kits.. (are you

a REAL developer). I got my ST development kit from Atari...it comes
with software and hardware schematics and phone numbers to call
if i need help. They
are currently working on a comprehensive software/hardware manual with
lots of examples.

sounds really closed and dishonest to me. Why don't you get your facts
straight.

>5) I have not heard much about ST expandability in terms of processors,
>more memory, etc. The Amiga was designed with such expandability in

Various people are working on 32 bit coprocessors...etc

>6) Most of the Dhrystone benchmarks run on the Amiga (showing slightly
>slower execution than the ST) have been run with the processor using
>(i am curious what drystones you looked at ...)
>the same memory as the specialized chips. With an expanded memory
>space (which could be desired for its own sake) performance should be
>enhanced, especially for graphics-intensive applications. A faster
>processor (the 68020) should give a greater increase in performance.
>What should really give floating point performance a boost is the
>addition of a good floating point processor chip (of which the 68881
>is a logical choice for the 68000 family). I expect a 68881 to be
>available for the Amiga long before the ST gets one (if ever).

i agree faster processors would probably boost performance. Though
it is interesting that when the ST out-performs the Amiga you are
so willing to go the route of "Yeah ...out in the future.... Amiga
will do such and such better"...the future may hold nothing but
chapter 11 for both companies...so i would value the moment more.

Lately I have seen some conversation on the net which I feel could be somewhat misleading. The first is that the ST is half the price of the Amiga. This is quite simply not true. First off, not every Amiga sold needs a monitor, this is not true for the Atari whos 70Hz non standard video rate requires that you purchase their monitor. This means that for people who have a TV/monitor or an existing monitor that will accept the Amiga output, an Amiga without monitor vs Atari with monitor comparison would be more accurate. This aside, lets try to compare two machines that are as close to the same as possible. In the interest of making things simple lets compare machines with color monitor and double sided double density disk drive and comparable memory. The Amiga as it is shipped now really has 512K built in, 256K of user RAM and 256 of kickstart RAM. The Atari has 512K of RAM of which 206K is used for the operating system. This leaves a little over 300K for user RAM. This is about comparable to (though slightly better than) a 256K Amiga. The double sided double density floppy lists out at about $100 more than the single sided floppy. If you add this up you get $1099 for the Atari and $1795 for the Amiga. This makes the Amiga about 63% more expensive. This is much closer to 50% than it is to twice as much. Since both machines can be discounted by a dealer any comparison of discounted versus non discounted prices is invalid.

The second thing I saw was a comment claiming that the Atari has special drawing hardware. I searched every article I could find on the Atari and while I found articles stating that it did have special display hardware I could not find even one reference to any special drawing hardware. As a matter of fact I ran across an article in Byte specifically stating that blitting was done in software in GEM.

The third point of interest is that several people have been stated that the method the Amiga uses to share cycles with the custom chips must slow the system down. Well, according to what I have read at equivalent screen resolutions and equivalent number of color bit planes, and with no drawing taking place the Amiga and Atari share cycles in an almost identical way. In both machines the memory cycles take place in two CPU clock cycle, since the CPU takes four to perform an access the display hardware steals the first two to do its thing while the 6800 is asserting its address and the machine is decoding it. The second cycle is then used by the processor. Both Atari and Commodore claim that this system has little impact on CPU performance. Furthermore, in the Amiga during the horizontal retrace time when the display hardware does not need memory, the disk and sound hardware get to steal display cycles. This means that unlike the ST which must use CPU cycles to transfer data to or from disk the Amiga transfers the data transparently.

Two things can make the CPU give up its even cycles on the Amiga, thus degrading performance. The first is if it uses 5 bit planes in low res mode (320 by 200 or 320 by 400) or if it uses 3 or 4 bit planes in high res mode (640 by 200 or 640 by 400). Since the Atari does not support these numbers of color planes you can only degrade performance by using a feature that the Atari does not even have.

The other thing that can make the CPU give up its cycles are the copper and the blitter. When the "copper" is running it is usually setting

up registers for the CPU. Obviously if the CPU were performing this task it would take it at least as long to do so. When the "blitter" is running it is doing drawing operations (lines, area fills or blt operations). Once a drawing operation has been set up, the blitter only needs to perform the memory accesses needed to do the drawing operation. The Atari on the other hand must not only perform those same accesses but must read the instructions that tells it to do them and must also read and execute instructions to do any ANDing, ORing and shifting needed to perform the operation. Anyone who thinks that the STs 68000 can do drawing as fast as the Amigas hardware has to have rocks in their head.

Now if you don't need high speed graphics (or for that matter expandability) then all of the above probably does not interest you. But if you are planning to use good, high speed color graphics or can afford the Amiga then it is the machine for you. Their also seems to be a consensus that all that graphics are good for is games. This too is not true, their are many applications such as CAD or Imageing that need good high speed graphics. I believe that many of these types of applications will prefer the Amiga

Because all the benchmarks are written in C. It appears that the ST has
a better C compiler available then the Amiga.

> "As for misleading advetising, did you know the Amiga has a meg of ram?
> That was my first reaction to the ad that says the Amiga has twice as
> much memory as a Macintosh. At least Atari tells you what exactly they
> are comparing against."

Now wait a minute. Atari doesn't exactly tell us what they are comparing
against. The 520 ST supposedly has 512 kilobytes of RAM- or so Atari
says in its ads, pointing at the 256K Amiga. But, ~ 200 kilobytes on the
Atari is used for TOS... and an Amiga (advertised as 256K) actually has
extra memory (about 200K, I believe) that *it* uses for *its* operating
system. At least Commodore tells us how much memory ya _really_ have.

Hi,

 Well, since you cross posted this, I feel obligated to followup.
I do not care to further the Usenet Amiga/ST debate, I just want
to correct some misonformation in Mr. Spangler's article:

> >On software availability:
> >
> >Lets see now. 520ST's became available in June and the software is now
> >ready in December.
>
> Uh, excuse me, but the Amiga was launched on July 23, 1985 --

Well, if you want to go this far, the ST was *launched* in January -
it became available to the public in June. The Amiga became available
to the public in October.

> >us all know where the relative priorities of software producers lie. I
>
> You know it's funny that you mention that now that Island Graphics has
> dropped the Amiga (which Commodore can't afford it seems). The thing I
> have seen of software availability is that there is *alot* of software
> available for the ST. Commodore admittedly has said that the software
> is lacking. Seems Comdex cleared up the issue of software -- for the ST
> anyway.
>

Island Graphics dropped completely out of the microcomputer market and
went off to mini/mainframe land. It was a decision not necessarily made
because of the Amiga.

> >... and I think its place in the market
> >is secure for awhile at least. But I don't tkink the Amiga is going away.
>

> There you go *thinking* again. Anyway, all flaming aside, I feel
> a sense of jealousy here. It seems that people here have to justify
> why they believe the Amiga is a better machine, because they can't
> believe that a machine like the 520ST exists.
>

Well, if you're not jealous, why did you write this article defending
the ST?

> You know, it was interesting to read the article in Inforworld (12/2) on
> "Christmas Contenders".
>   "Observers have noted some clear distinctions between

>
> Aloha,
>
> --
> Jonathan Spangler
> {ihnp4,vortex,dual}!islenet!jons
> "On Thursday, the world came to an end."

>

Wow, you read InfoWorld! - I hear it's a great magazine!... (ahem)

Gossip is gossip - using comments from Jack Tramiel and the folks at
InfoWorld is hardly unbiased concrete evidence. Talk to dealers yourself
and you'll find most Amiga owners so far are hard core hackers (and yes,
there are many first time users buying it because they want the leading
edge of technology). The ST is a great machine for the price - I
recognize it's existence (yes, in public!). There is some good software
coming out for it (most from England I believe), and I hope it does
well in it's market niche. Please don't compare it to the Amiga, the
two are wholly different beasts, save for the fact that both have a
68000 and both can do some nice graphics (we are treading on thin lines
here).

 I sincerely hope this is my last message posted to net.micro.atari -

I hope everyone will start concentrating on making some really
constructive contributions to their own newsgroups *soon* !

Eric

Summary: OS-9 is coming anyway

     Dave Fetrow asked if there is anyone working on a Unix clone.

     OS-9 isn't really a Unix clone, but I'd guess it would be according
to his description. I assume you have missed the previous postings.
OS-9 68K appears to be coming early in 1986. This is very auspicious
because, although I probably won't be getting an Atari myself, I *will*
likely have an OS-9 68K system by then. Sinclair already has OS-9 68K
available for the QL, and there is a fair body of software developed and
in the works for it.

                                        Cheers! -- Jim O.

>>
>> When I got through to them, they told me over the phone "That's the
>> price for the CPU only, the package is $699."
>>
>
>   We called them (their 800 # has been dis-connected) and asked
>about the price of the 520st. We got the same story at Bob Halloran,
>however, we have one additional comment to add: the package with the
>color monitor is $899, a far cry from $369. In case anyone else wants
>to give them a call, their number is 212-947-5290. It might not be a bad
>idea if you folks in the N.Y. area give these "people" a call and express
>your dismay at their price (and false advertising). They might have
>second thoughts the next time.
>
>   Polytech U.

     There may be another possible solution. If you can put together a
system based on the CPU which is better, then do it. If this company
has to buy the computer bundled anyway, then they'll be stuck with a
pile of monitors, etc. which they'll eventually have to discount even

further. Never act out of anger when a situation can benefit you with
the application of a little imagination.

                                        Cheers! -- Jim O.

I just read in infoworld that AT&T have signed a deal with Atari to release
the 520ST under their label with the UNIX V operating system. I have also
heard numerous rumours that this machine will come standard with monochrome,
20meg hard drive, 1 meg onboard, and will sell for $1000. Can any of you
people who work at AT&T either confirm or deny any or all of this info. If not,
how about a clue????

>
>-Zigurd

One reason you probably have not heard too much about relative merits of
the O.S.'s is that most of the people on the net may be programmers who
may feel that this is irrelevant to the performance of the machine.
Not to imply that the O.S.'s may have no effect on performance, but
even if the O.S. is bad for a particular machine, you can always
discard it in favor of something better (OS9 perhaps etc.), and it
is the underlying hardware that is the important factor. The ST may
not have a multi-tasking O.S. now, but that could change next rev. etc.

In addition, you may have not heard too much about the ST's O.S. from the
ST camp perhaps because they are aware that CP/M has never really been an
O.S. but just a sophisticated loader. And, once your program gains
control, CP/M does so little for you it might as well not even be there,
especially as far as performance is concerned if you are not doing CP/M
calls.

Oh OSI, oh OSI

(to the tune of O Tannenbaum)

Oh OSI, oh OSI,
Your rules are always changing.
Oh OSI, oh OSI,
Your rules are always changing.

Each year you bring new protocols,
More overhead and service calls.
Oh OSI, oh OSI
Your rules are always changing.

Oh OSI, oh OSI,
With seven layers burdened.
Oh OSI, oh OSI,
With seven layers burdened.

No matter where I turn to look,
There comes another colored book!
Oh OSI, oh OSI,
With variation, sagging!

Oh OSI, oh OSI,
The source of my frustration!
Oh OSI, oh OSI,
The source of my frustration!

A plebescite in 92
Will split a layer into two;
Oh OSI, oh OSI,
Amoebic reproduction!

Oh OSI, oh OSI,

Eternally unfolding.
Oh OSI, oh OSI,
Eternally unfolding

Oh, can the C C I T T
and I S O at last agree
On OSI, on OSI,
The final net solution?

Oh OSI, oh OSI,
Ever in negotiation!
Oh OSI, oh OSI,
Ever in negotiation!

Perhaps one day I'll live to see
A multi-vendor community!
Oh OSI, oh OSI,
With endless promise laden.

Oh OSI, oh OSI,
Your rules are ever changing.
Oh OSI, oh OSI,
Your rules are ever changing.

What's wrong with advertise the information about the program on the ne?
If somebody like me want that kind of program badly, he probably need
that right away and save time to seek information. Nobody will blame
the author because he advertise some product on the net which cannot
easily be found everywhere else.

Some pretty nasty stuff here. Bu facts are facts: Atari was once a $2
Billion company, and a year later was sold to Tramiel for $75 Million, and
the ASSUMPTION of a LOT of debts Atari had run up. Also, what do you expect
software publishers with ST products (or Sam Tramiel) to say in InfoWorld?
Flaming someone's statements is typical on this group it seems, but flaming
the person himself is pretty low. Both machines have great technology for the
money, it all boils down to how much money you want to spend, and how much
you value things like more colors, better sounds, multi-tasking, or some
of the other features that the Amiga has over the ST. The ST is a great
machine for the money, which is something that some of us Amiga owners

seem to ignore. Now lets be nice...
(as he gets off his soapbox and falls flat on his face...)

     Sounds good to me. Besides, everybody KNOWS that their choice is better. :-)
But then again, what do we do when someone needs to know which one is best for him
or
her? Not say anything for fear of being flamed to death??
     I think this topic should be given a rest, but not totally killed. If you
don't
want to read about it, you can always type in an "n" to move to the next article.

AND HE THROWS UP HIS MIGHTY ASBESTOS SHIELD!!

    Please, no 300 Baud flames about how much longer that will take, I KNOW how
much
longer it will take, I have to use a 300 Baud modem at home. We just can't cator
to
everyone 100%.

HE LOWERS HIS SHIELD, HIS POINT MADE.

    And now let me end this, so I won't get flames about it being too long.

                                        Rodney

What will happen next year ?

Here are my 1986 predictions for the Amiga, ST, MAC.

The Atari 520ST will come standard with 1 megabyte of ram
by June. Also sales will be better than most people think
(200,000 units per month). Atari will also be in the OEM
business (low cost UNIX based CAD-CAM systems), probably
in partnership with a large company. Experts will be
amazed that there really is a HOME computer market that
nobody has been able to find (until the ST).

Amiga sales will be slower than expected but good enough
to keep Commodore going (15,000 units per month). The
Amiga will also come standard with 1 megabyte of ram.
Sales will be very slow in first quarter 86, but will pick up
when the Amiga gets a 30% price cut.

There will be plenty of software for the Amiga and the
Atari ST, but as usually is the case, (look at the old
Atari 800 systems) it will NOT take advantage of Amiga's
Graphics hardware. Large software companies like to write
portable code. Smaller companies will write the Good Stuff.

Apple may be in VERY DEEP trouble, but with Fat MACs for
$1500.00 and the new APPLE IIxt 16 bit computer that runs
in two modes ,8 and 8/16 bit, will pull out of trouble.
The new apple will use the new 8/16 bit 6502 micro.
It looks like the first Personal Computer will never
die, (who says you can't teach an old dog new tricks).

Appears unlikely???? AT&T just signed a licensing agreement with Atari to
listen UNIX system 5.0 to be run on the ST's. I just read this in the most
recent issue of INFO-WORLD. As far as I know, this supports multitasking and
multiuser and is not just a UNIX shell.

I have a few questions about the ST that I hope someone will be kind enough

to take the time to answer:

1) Can the GI AY-3-8910 programmable sound generator (PSG) be used as a D/A converter? My information from GI's catalog is incomplete. It seems there are three 4-bit (lo-fi, anyone?) logarithmic D/A converters on the PSG that normally take tone generator inputs, but there is an amplitude control register that specifies a 4-bit amplitude plus a 'mode' bit that the data sheets don't describe. My guess is that one of the modes tells the D/A to just output the 4-bit value in the register. Anyone know?

2) Is there a way (say from BASIC) to turn off all graphics DMA (similar to the DMACTL register of the 400/800)?

3) What is it that causes INTERPC's terminal software to crash the system (usually)?

Thanks in advance,
cbosgd!nscs!jmk (Joe Knapp)

Summary: Question on ST printers

Can I please get some replys regarding what kind of printers people are using with their 520ST's. I am particularly interested in ....

1. Price
2. Printing speed
3. Does the printer do high res. graphics
4. Does it do letter quality
5. Are you using the parallel port
6. Where did you get the software driver for the ST-printer.
7. Good points, and bad points of the printer.

ANy replys or information would be appreciated!
     Thanks.... Peter Espen.

FLAME ON****

Did the IBM PC have an abundance of software when it was
introduced??? NO!!!! Did the MACINTOSH have an
abundance of software when it first came
out??? NOOO!!!! In fact, as I recall, the macintosh
didn't have an abundance (relative) of sotware for a whole
year. A couple of friends of mine had nothing but
macpain (the drawing program) for a long time.

So give the Amiga a break and wait a year. I am sure the
software base will grow exponentially (so sure in fact, that
I bought one)

I was over at my local computer store the other day, and they
say that the IBM PC'S and the MAC'S are the Amiga's
best friend. They told me an amusing story about how
this one lady came in to buy a MAC and happened to see
the Amiga, with it's limited software base, running some graphics
program. So what happened??? She bought the Amiga.

Larry J. MacCaughey (No relation to the MacIntosh)

excerpts from "Hands ON! (Guided Tour of a `Real Live' Amiga),
          Ted Drude, Computer Shopper, January 1986

..Unfortunately, at this point, the Amiga has some weak spots from its "rushed
introduction. The lack of useful programming documentation for the Amiga is a
case in point. Another problem is little or no software for average users (and
many developers). In time these problems will be rectified, but for now, they
can be frustrating for someone who's just shelled out two grand or so for an
Amiga.
...MicroSoft BASIC was supposed to be shipped with the Amiga, but it wasn't done
in time.
...Like alot of Amiga documentation...it hasn't been released to the public yet

(this is getting ridiculous).
...AmigaDOS is a fantastic multi-taking DOS that is a perfect complement to Amiga's great hardware. Unfortunately, all the details on how to use this DOS for programming is found in the (you guessed it) not-yet-released-to-the-public "AmigaDOS Reference Manual." Almost no DOS information whatsoever is provided in the error-laden User's Guide.
...includes "ABasiC," or Amiga BASIC interpreter. The label on this disk also mentions an "Amiga Tutor" program but it isn't included (yet). ABasiC seems to be a good BASIC interperter...[but] it also has some problems in that it uses a limited line-editor instead of a full screen editor (quite a let-down for Commodore users) and it has some small bugs in it. But at least Commodore included a programming interface with every machine (which is more than can be said for Apple and its Mac).
...The worst part of ABasiC is that the "Amiga's User Guide," which includes a section detailing ABasiC, is full of errors. Many of the syntax descriptions and examples won't run because of obvious typographical errors. This is a further indication of a rushed introduction for the machine.
...One thing that isn't included is the fancy graphics demos you see on the Amiga TV commercials. The "bouncing ball" demo, for example, isn't included. Supposedly, it's for dealers only. Be nice to your dealer, and he may give you a copy to impress your friends with.
...The disk drive seems to be a tad slow for "hyper-DMA transfer", but not as bad as the Macintosh's lethargic drives.
...If you're doing any serious software development, I think a second floppy drive is almost a necessity. When copying files between disks on a single drive Amiga, you are prompted many times to swap disks. A second drive eliminates this. A hard disk would also be a big improvement. (Tecmar has a 20 Meg unit due for shipment "real soon now." Price: $1200 or so.).
...Some of the Amiga's pins [on the serial interface] have voltages on them when they should be grounded or no connection. Make sure you check the printer or modem pinouts against the Amiga's documentation before connecting or you might run into some problems...
the two video chips (`Denise' and `Agnus' are the most interesting.
Just how you get those graphic chips to work in your programs is somewhat difficlut to understand, to the uninitiated, but Commodore promises to reveal all secrets..in time. Right now, only those on the Commodore-approved "developer's list" can get that information. (Booo!)
...the more colors on the screen at once, the more Ram and processor overhead is required to maintain them. So even though 4096 are possible, the Amiga usually only displays about 16 or 32 different colors at once.
...Some Amiga owners are using Sony RGB monitors. Sony has a line of "super hi-res" analog RBG monitors that even Commodore is rumored to have been using for their own development work.
...If you're on a budget, you might look at the Commodore's other monitor, the 1902...Some claim that [the 1902 and the Amiga monitor] are the exact same monitor with only a sticker on thr front being different. Since the 1902 is running for $250 or so at discount, and the Amiga monitor is selling for $500 at retail, you might buy the 1902 if you can stand having "Commodore" and not "Amiga" on the front panel of the monitor. (By the way, don't expect your Amiga dealer to either know this or tell you about it.)
...If you're on a very low budget, you can hook your Amiga up to a TV set (throught an RF modulator) or a composite monochrome monitor. But, I'd wait until I could get an RGB monitor. I mean, the hi-res color graphics are more that half

of what the Amiga system is all about, anyway. Anything less than an RGB monitor on an Amiga is like training wheels on an F-15 fighter. Why hold back the potentional if you're going all out? It defeats the purpose.
As a final note on the Amiga monitor, the initial specs for it included a stereo audio amp. Well, it ain't there. You only get mono. You have to use a "Y" connector to get both channels hooked up to the mono amp. Of course you can hook the two Amiga sound output channels up to your stereo and skip the wimpy little monitor speaker, anyway.
...the Amiga's video chips can only access into the first 512K of RAM, so all graphics and display memory have to be there too. In a 256K machine, things start to get tight real quick. You will usually have a lot less than 190K left for programming, especially when running animated graphics. For this reason, most of the fancy graphic demos for the Amiga need 512K to run.
...If you are doing software development, you should consider getting the extra 256K at purchase time (a $200 option). If you aren't writing fancy graphics programs yet, that extra RAM can also be put to use as a RAMDisk.
...Documentation and Price -- The Downfall of a Hero?
So, while the Amiga has a lot going for it, and I do mean a lot, it aslso has some temporary (I assume), but serious shortcomings. Like a shortage of available applications software, little technical documentation (remember, this is a real production model I saw, not a "for review" prototype), and a price that will keep it out of the traditional Commodore markets (for a while). As long as these shortcomings are not addressed by Commodore, I think the Amiga will be a slow seller, and an apparent flop to "outsiders" (i.e. those who aren't Commodore "true believers").
The high price, especially will be a hindrance, because the Amiga is going to experience head to head competition (and comparison) with a computer from Commodore's life-long nemesis, Atari. The Atari 520ST doesn't quite have all the sophistication of the Amiga. But it has a fair amount of it. That may be enough to sell it to those who "want an Amiga" but will "settle for an Atari." The same technique worked well with a lot of people who bought a Commodore 64 instead of an Apple II. In my opinion, the Atari will have the marketing edge as long as there is a price difference between the two of several hundred dollars (currently it's closer to $1000 difference).
So, I hope and expect Commodore to get the price of thae base unit under $1,000 in the next year. When that happens, sales will pick up and the software will flow. Until then, expect to hear more success stories about the Atari than the Amiga.
...[cost is] almost two grand for a system with no printer and precious little software! We aren't talking about a little game machine for the kids anymore. Trying to get a discount on this thing is useless. The demand is still too high.

Development Package -- Promises from Pennsylvania. If you are lucky enough to get the "Developer's Package," a lot of the documentation problems will be solved. There may be some errata to contend with, but at least you won't spend hours (like we did) trying to discover the right syntax for CLI commands...Good luck trying to get one.
If you are willing to be a pioneer and take a risk, becoming one of the first Amiga owners might pay off. If you can stand the lack of software and documentation, the arrogant attitude of Commodore towards average Amiga owners, and the reproach of being a non-conformist, you may find that mastering one of the most powerful personal computers ever built...can be an exhilarating experience.

Just reading the news, although I would be interested in what you think about
Mr. Drude's comments on the Amiga.
I think he has said all I would have wanted to... blessed are the
Volkswagens.

Aloha,

The //x (which is the name [I think], not the IIxt) may not
become an entity. There is a company selling cards for the
//e and //c that essentially turn them into //x's, with
65816 and 1meg RAM. And it goes for $400! So what I hear
from a friend of a friend who has indirect connections
with Apple is that no //x will be made, at least this year.

Summary:

In article <4301@topaz.RUTGERS.EDU> eric@topaz.RUTGERS.EDU (Eric Lavitsky) writes:
>Wow, you read InfoWorld! - I hear it's a great magazine!... (ahem)

The latest issue of InforWorld reviews the Amiga, and is a real detriment to the Amiga. Not only did the article contain several mistakes, but they reviewed version 1.0 of the workbench and kickstart, which we knew had bugs. Now, 1.1 has been out for a few weeks, and I have not really had a whole lot of trouble with the software crashing. My Amiga crashes all the time when I pass extra parameters to function calls, etc., but during normal use, system crashes are rare.

InfoWorld also talked mostly about the 256K machine, which is like reviewing a 64K IBM PC. The Amiga is an 8+Megabyte of RAM machine, and those of us who own Amigas are just licking our chops waiting for the equivalent of an AST card. The Amiga with 8+ megabytes and the 68020 should be compared with the IBM AT and MicroVax. InfoWorld did review what they had available, but we who read net.micro.amiga and net.micro.atari seem to be better reporters of the state of the Amiga (and ST as well) than the "Professionals" at InfoWorld. I hope to see another review next week, since the new software is so much better. Also, InfoWorld did not mention any of the software packages that I saw several weeks ago at Computer Attic, when I bought my Amiga almost 3 weeks ago! Yes, they probably have some lead time, but to write TWO FULL PAGES about a machine that they couldn't even try any software out for, and then make statements like "As an aside, we forsee a flood of bad software written for the Amiga by programmers unaccustomed to multi-tasking programs..." is pretty stupid, if you ask me. They also put an "Editor's note:" at the bottom saying how they had a "lack of cooperation from Commodore." I wouldn't expect Commodore to cooperate with InfoWorld because of several degrading articles (John C. Dvorak, and others) about Commodore and Amiga. Also, the Amiga was given 2 terminals.

Now to the defense of Infoworld, they did have some nice things to say about how Intuition was as friendly and easy to use as the MAC.

Please note, this article is very comparable to Infoworld's, except turned around so that InfoWorld is the one getting roasted. InfoWorld did not even mention a single piece of software that we have all been seeing and hearing about since they were anounced and demonstrated at the June launch. Off the top of my head, I can think of Flight Simulator, the digitizer, perhaps 10 different Electronic Arts titles, Chang Labs (InfoWorld gave their IBM PC software good reviews) has some business-type software (I saw an accounting and general ledger package), or any of the other products demonstrated at the launch. Where was InfoWorld at the launch? Didn't they see anything then? Couldn't they call Chang Labs and ask for software for evaluation? Couldn't they do any investigation at all?

Another quote: "Judging from the number of beta-test programs floating around, we can expect to get a chance to judge the software side of the Amiga system a lot sooner than we could when the Macintosh was first introduced." Well, in June, the Amiga had more software packages announced (with real live developers working on the stuff) than any other PC in history - including the Mac, IBM PC, Atari ST, Atari 800, Commodore 64, et al.

I have been reading InfoWorld every week for a couple of years, and never noticed anything like this before. Typically their articles are real good. In the same issue as the Amiga review, they review Apple's new 20MB hard disk. It costs $1500 and is "two or three" times faster than the floppy disk (oh boy, now it only takes 1 minute to load a word processor instead of 3 minutes) and they (InfoWorld) gave it 3 (count 'em) terminals. Sounds kind of biased (just kind of) to me...

Sorry to be so long winded...

/mykes

Summary: Misleading Infoworld Article

In article <2664@sunybcs.UUCP> ugjohna@gort.UUCP (John Arrasjid) writes:
>I just read in infoworld that AT&T have signed a deal with Atari to release
>the 520ST under their label with the UNIX V operating system. I have also
>heard numerous rumours that this machine will come standard with monochrome,
>20meg hard drive, 1 meg onboard, and will sell for $1000. Can any of you
>people who work at AT&T either confirm or deny any or all of this info. If not,
>how about a clue????
>
>John Arrasjid   SUNY/Buffalo Computer Science

Well, this little rumor was enough to make any Amigoid shiver in their boots, so I decided that I had better try to find a copy of Infoworld and see

what the article said. Well, it's on page 3 of the December 23 Issue, titled 'Atari, AT&T Reportedly in Deal for Low-End Unix Machines'. I would urge any interested persons to read it for themselves, since I don't want any Infoworld lawyers on my case.

The article states the AT&T has agreed to purchase ST's for use as low-cost *TERMINALS*, not unix machines. I would be the first to admit that the ST would make a great cheap (color?) graphics terminal. The article also states that the ST's would be specially modified, I suspect by putting in special ROM's that leave out the OS functions and include, perhaps, BLIT terminal emulation.

The article then resurrects some *OLD* Atari statements. One is about some unix based *applications* software that was supposedly going to be ported to the ST. The other relates Atari's announcement back at Comdex that they had purchased a Unix Source License.

This doesn't mean that Atari is going to planning to port unix to the 520ST, it merely means that someone at Atari was able to justify the $$$ to buy a source license as part of their overall development effort. It also doesn't make them the only or even the first company to buy a System V license.

I've previously rebutted some postings that you couldn't port unix to the ST, but that doesn't mean that Atari will do it, and this article does not announce any such thing.

Summary: Atari OS is not CPM68k

>Keith Doyle

The TOS operating system is not based on CPM68k. It is instead derived
from MS-DOS. The reason CPM68k was rumored as a basis for TOS is that
the C-compiler that comes with the development kit was ported from
a CPM68k environment so the runtime library has some remnants
of CPM68k conventions. By the way the ST does have multitasking of
a sort. Basically the processes have to call a get event routine that
then calls the next routine on the ready list. The basic idea is
to have one main application program and the desk accessories
share time so that one can have printer spoolers, etc.
running in the background.

I am very annoyed at the basic that I got for the ST.
I've just finished writing some 16K of code that disassembles
68K code. The program is really nice. But it doesn't work. And I have to
blame the tools: this BASIC is pathetic!!!
Having identified numerous important bugs and written the program
to specifically to avoid these, I've found that the interpreter just
can not handle strings. It just messes tham up completely. The problem is
string assignments. Strings are read in nicely from disk files. I have a
program on disk which is written in an interpreter language which I wrote
specifically (ie I designed the language) for disassembling 68000 code.
The Basic program of some 450 lines acts as interpreter for this disassembly
program, representing each line of the file as a string. First I read the file
into an array of strings. And then as I execute each line, I need to assign
the string to a temporary string in order to use it. But the Basic interpreter
can not even read the string in an array into a fixed string. It also
messes up lines like
kk$ = right$(kk$,len(kk$)-1)
[and] kk$ = right$(kk$, k)
Either there is something obscure I don't know about BASIC or else this
interpreter has a problem with management of the space allotted to strings.
It keeps overwriting where it shouldn't in the string working space.

At first I thought it would be a good joke to decode 68k using a Basic program driven by another program written in an interpreter language. Then I thought was it was not such a great joke when I realised that I would have to keep rewriting things to avoid the bugs. I thought that eventually I would use my disassembler to disassemble, dismantle and fix the BASIC. But it seems to have enough bugs to prevent anybody from easily finding the bugs. And I'm not going to hand disassemble a 130k interpreter.

How could anybody possibly run anything on such a BASIC???

Surely DR knew about all the bugs. I know they were pressed.

But now I'd like to ask just one question. When is BASIC REALLY going to come out for the ST??? I mean one with a tolerable bug level!!!

Alan Kennington.

PS I only use basic because it's there. As soon as my dev kit comes, I'm going to fix the bugs in Basic and then put it in the trash.

"Gentlemen, we have the technology to rebuild BASIC."

Update to previous message about ST BASIC: The strings are not completely irretrievably useless. One just has to replace statements of the form:

```
a$ = right$(a$, len(a$) - 1)
```

with statements of the form:

```
b$ = a$ : a$ = right$(b$, len(b$) - 1)
```

and then everything works okay. And then when the real BASIC comes along, such hopeless code can be removed. Luckily Basic is so slow in the first place that inefficient code doesn't make much difference.

I'm collecting quite a list of Basic bugs now. But since real programmers don't use Basic, I won't bore you with the details.

Does anybody still program in Basic, or is that just for kids and hand-held portables like the Sharp EL-5500II, with its magnificent

3.8k of RAM??   ....ak

/* Written 9:18 pm Dec 25, 1985 by ugjohna@sunybcs.UUCP in net.micro.atari */
I just read in infoworld that AT&T have signed a deal with Atari to release
the 520ST under their label with the UNIX V operating system. I have also
heard numerous rumours that this machine will come standard with monochrome,
20meg hard drive, 1 meg onboard, and will sell for $1000. Can any of you
people who work at AT&T either confirm or deny any or all of this info. If not,
how about a clue????
/* End of text from net.micro.atari */

Because <enter dripping red font> V <exit dripping red font>: the
System, like essentially all versions of Unix, relies heavily on memory
mapping hardware, the current 520ST will NOT support it. This is not
to say that AT&T might not write a version of "the standard OS for the
world" <heavy sarcasm> that doesn't require it, but it would be a
considerable effort, and I doubt that such a thing will happen. It's
probably easier to persuade Atari to redesign the ST.

I wouldn't mind seeing the ST those rumors describe--it would be a nice
machine to run OS-9 on when (no longer if, it seems) it comes out for
the ST.

Keywords: Atari, ST, UNIX , hpux

For all those skeptics that cannot believe that the ST
can't support UNIX, I suggest you look over the Hewlett-Packard
68000 based computer line. The Series 200 can run hpux (purported to
be system V with bsd enhancements) in as little as 1 Mbyte of memory
and a 10 Mbyte Winchester (sound familiar?). They support a ROM based
UNIX in a PORTABLE! The largest problem with hpux is the licensing
fee (to satisfy AT&T) which is passed on to the buyer. I don't remember
any special memory management hardware in these machines. Again, these
are single-user implementations of UNIX and may not support some of
the features which dictate the need for memory management hardware.
As a user of these systems, I look forward to a ST-UNIX box (atux?).

From my experience with the AY-3-89something on Apple computers, that mode
bit simply selects the automatic envelope generators as opposed to manual
amplitude setting through these 4 bits. I tried sending white noise
through and modulating it with the 4 bit amplitude control; it doesn't
sound like D/A would.

     Someone mentioned once how to avoid the problem of the EOF test
not being valid, due to a bug in ST BASIC which somehow made the first
byte of a file unreadable and hence got the byte count wrong. Well, I have
something new to add to the list of file reading bugs.
     Suppose you have a 20K BASIC program loaded in and you use it to
read in some file. The first time, the aforesaid bug is evident, and a check
for ERR = 62 resolves the problem. But if you do a bit of editing (to cope
with other Basic bugs) and then rerun the program, you get some sort of
"Undefined error at line 740", where 740 is the line where you first

try to read in something. And the punchline is that the third time, the file seems to read in perfectly. It even gives you the very FIRST elusive byte of the file. (I saw it with my very own eyes!!) BUT when you go to use what you've read in, you find that the strings read in have got other strings written all over them. So the solution is to clear out all of the string space before doing any input using Basic.

So now there are at least 3 distinct failure modes for an input routine to cope with. Now that I have identified them, my disassembler is running beautifully. But it just shows what can happen when a company is too keen to convince the market that software exists.

My next step is to dump the operating system to see how it works, and then start writing an assembler and start programming. Of course, if my developer's kit comes first, I might be able to skip the assembler writing stage. .....ak.

Hal Hardenbaugh of Digital Acoustics used to publish a newsletter called "DTACK Grounded". He now occasionally mails his former subscribers a newsletter of the same name that he refers to as junk mail. Hal has long been a fan of the 68000, but not of the Macintosh or of the Amiga.

He is writing a BASIC for the ST called HBASIC, which will sell for around $80. His primary complaint with the current BASIC is that it takes up too much memory. The only thing is, Hal is apparently going to circumvent much of TOS for his BASIC. He claims it will leave 400K free for programs and data. Don't know when it will be out. I believe Hal is based in Orange County, California, but I don't have the info handy.

>Surely DR knew about all the bugs. I know they were pressed.

I understand that Metacompco was the original author of Atari's BASIC. I don't know if DR ever had anything to do with it.

Steve -

     The correct order is:

     @B O S   (Binary Output Start -- binary to user from TAC)
     @B I S   (Binary Input Start -- binary to TAC from user)

      Binary Input Start disables any TAC commands from the user until the connection is closed.

      On certain advanced operating systems (e.g. TOPS-20 systems with the PANDA MODIFICATIONS), there are user commands which accomplish the same effect and hence you don't lose anything by using them. On the PANDA TOPS-20's (SIMTEL20, STL-HOST1, and DREA-XX), the command is

TERMINAL [NO] NETWORK-BINARY [INPUT | OUTPUT | BOTH]
The word "NO" after "TERMINAL" disables binary mode (else it is enabled),
and the default binary mode is both. There is also a system call to do the
same thing.

Perhaps some bright Unix hacker can figure out how to put this in Unix.

[]
A few questions about the ST from a prospective customer:

What's the deal with the disk drives? I understand that with
the default $700 monochrome package (monitor, cpu, keyboard,
and disk drive) the drive is a single sided 360K one. Are there
also double sided drives available? If so, can you get a double
sided drive instead?

Is a development system (full documentation + a C compiler)
easily available? How much does it run?

How much would a 1200 baud modem + a smart terminal emulator
(if any exists) run? Any recommendations for particular brands?

What's the last word on hard disk availability?

Hope to hear from all you ST owners out there. If the replies
are interesting enough, I'll summarize to the net.

Hybrid Arts is working on Patch Librarians and ST versions of MIDITRACK III- a 16 track sequencing program that currently has been implemented for the 130XE and the 800 line. I have the 130 XE version and it is great you can do cut and paste editing, delay tracks, looping, lock to a variety of sync sources, More!!!. Hopefully the ST version will include some better graphic displays and make use of the other advanced features of the ST. They've done a good job in the past.

Atari Coin-op people don't really have anything against DEC. One of the
programmers on the Mojor Hovoc project added that one day when the 780
they were running on was exceptionally slow. The higher ups didn't know
what Evil Vaxxion Empire ment so they left it in the game.

    I hate to have to say this, but my owner's manual has clear (enough)
instructions for inter-disk file copying on pages 53-54:
    "If you want to put a copy of a file onto another disk, drag the
icon over to and on top of the icon for that disk." etc. complete with
semi-mockup photo/printout of aforesaid activity.
    But rather than clog the phone-lines with items about what people
have found out that is not in their manual, it would be a nice idea to
have some bull. bd. somewhere on which to deposit the accumulated

discoveries from people actually using the machine. In the Amiga group
there seems to be plenty of the kind of information you encourage.
It's a mystery to me why nothing so constructive appears here.

Keywords: Panasonic 1092, dot matrix, near letter quality, $329
Summary: Panasonic 1092

The printer that I feel is best for the ST is the Panasonic 1092. It retails for around $400, but I've seen it as low as $329. It is 180 characters per second, has draft, condensed, near letter quality, proportional draft, and proportional near letter quality modes selectable from the top of the printer, not to mention more from software. It takes single or tractor feed paper, and will automatically advance the paper to the paper bail for you. The tractor is behind the paper roller so that you don't have to waste 1 sheet of paper like with most other printers. The mode that it comes with is Epson compatible and it also has some IBM modes.

It seems to work fine for screen dumps and works with ST-writer, 1st word, and Final Word. It supports the international character set as well as graphics characters. You might have to wait a few weeks if you order one as I'm told they are nationally back ordered.

   It's just people discussing what a wonderful machine this would be *IF*
it had a 68020 and 8+Mb of RAM, and especially how much better this would be
than today's ST. 1/2 :-)

A friend just told me he was expecting Atari to introduce a "TT" line of computers- the "TT" standing for "thirty-two/thirty-two", using possibly National Semiconductor's 32326 (or something) cpu. He said that it would be so fast, so wonderful, that Atari could "emulate anything else by brute force if it wanted to." The machine supposedly would "run UNIX."

Anyone else heard of this beast? (Post replies to net.micro.atari, and net.rumor I suppose.)

Well, I have decided now that I am probably going to get an
Atari 520ST in the near future (in case you care, the main
reasons for my decision, when comparing it to the AMIGA, were
the price and the high-quality 640x400 display mode).

(One thing that I noticed is that the 520ST has a little
bus-connector on its side. What signals are available on
that connector?)

I have a few questions, and I am sure that others might be
interested in these as well:

-- what is the cheapest place to buy? I know of a place in
   Cambridge that sells it for $650 (monochrome, ss drive).
-- how pressing are disk-space problems on the machine?
   The dealer disk had a TOS image that was 200k big. Can
   that be stripped down? Are the tools to strip it down
   available? What configuration, a ds drive, two ss drives,
   or a ss and a 5 1/4" drive would YOU recommend?
-- what off-the-shelve development software do you know of
   and would you recommend? I have seen (at various computer stores):
   -- 4xFORTH
   -- HiSoft Assembler
   -- MetaComCo Assembler
   -- Haba C
   Do you have any experience with these? Are there other
   packages available?
   In particular, I have heard that Haba C has some severe
   problems. Is there hope that they'll be fixed?
-- what word processors do you know of/would you recommend?
   I have seen 1st-Word, and it looked decent, although
   not impressive.
   It would be very helpful for me if I could configure the
   processor for my printer (an Imagewriter II).
-- what MIDI software and hardware do you know of for the ST?
-- what commercial RAM upgrades are there? Is there a 1M version
   of the computer being marketed in the U.S.? In Europe?

                        Thank you,
                        Thomas.

Summary: 1meg st

An article in USA today (12/30/85) talked about Atari announcing that the
512k st would be sold in chain stores, and a 1 meg version of the st would
be carried by those stores currently carrying the 520st. Sounds like the 260ST
will be dropped!!?!?!!

Also, it appears the TOS rom chips will be going for about $20 and that they
will be shipped any day now. Gary Tramiel provided this info (TOS chips) to
my boss at a local store.

Dear Netters,
     Has anyone got the specs for the DMA port yet? If so where did
you get the information? Has anyone verified that there is an easy way
to convert it to SCSI? Yes, I have the January Byte.
     Please post or mail according to your feeling about general
interest in your information.
Doug.

I just got the KERMIT file transfer protocol files and was delighted
and ready to put them in when I saw that I'd have to have the ACTION!
language cartridge in order to do so. Also, because Atari's DOS II
destroys the T: and R: drivers, I have to recompile the programs before
I can run them each time. The suggested alternative was to build my
own AUTORUN.SYS which would compile automatically the stuff, and save
me time. Does anyone know how I would go about writing such a system?

And what software I need? (remember please I am a very new Atari owner
with an 800XL --> please don't look down on me, ST owners).

Also, I know that they'd LIKE Me to get the cartridge rather than have
action! put onto a diskette, but is it possible to have someone put it
on diskette for me? Would I still be able to run the stuff? and compile
it?

Ignorantly yours,

Randy Magruder

what about all the relocation fancy footwork that unix does
to handle the per process data area
what about multiple processes
are we proposing going back to the dark ages of rsx (unmapped)
where programs were linked for different load addresses
memory mangement is required for two reasons
protection and reloxcation
the first you can live without (that is if you never have pointers
which point nowhere)
the second is kind of hard to live without

At last...an 8-bit question!

Can anyone discuss the relative merits or otherwise of OSS's ACTION! cartridge
vs. their C/65 compiler. Which would you recommend I purchase? I know that
C/65 requires MAC/65, but that's ok. I'm more interested in things like
ease of programming in one lang vs. the other, development environment
provided, known bugs, speed, etc. I'm leaning toward C/65 mainly because
learning C at least would be of use with other machines, whereas ACTION!
is presumably of no use outside 8-bit Atariland. I have an Atari 800.
Posting replies to the net would probably be appropriate here. Thanks.

Several people have asked me where in Cambridge one can get the
Atari 520ST. Well, the address and telephone numbers is:

     MetroServe Computer Company
     312 Broadway Ave., Cambridge
     491-0908

When I first called them a few weeks ago they quoted a price of
'roughly $650' on the 520ST. I just called them again, and now (?)
the price is $700 on the monochrome system, and $900 on the colour
system. If you want ds instead of ss drives, that is $50 extra.
There is no further student discount, because 'these prices are
special sales prices', they say. They don't have any ST's in stock,
they say they sell them as they come in, and there is a waiting
list of about 2 weeks.

Needless to say, I'm not in any way connected with MetroServe Computer
Company, other than having called them twice. I've neither seen
their sales offices nor bought anything from them. So if you find
out anything about that company, let me know. Except for the Lechemere
store in Cambridge, which only sells the colour version (expensive!),
this seems to be the only place in Cambridge that sells ST's.

                              Thomas.

PS: I would, of course, still be very much interested in any place that
sells the ST for less than $700, even by mail order. Someone on the
network quoted that he got it for $600. Was that a special deal with
the university?

An earlier message on the net implied that TOS in ROM might be available
by Christmas. Not seeing any evidence of this, I called Atari. They said
the ROMs would be available in two more weeks. Someone else confirmed that
he expected to buy the ROMs from his local dealer in mid-January.

Is anyone using the EPROM version of TOS? If so, how does it look?

/*   ------- If swallowed, call a usenet hack immediately --------   */

     This is the documentation for the public domain assembler that
     I posted a few minutes ago.

------------------ Cut this line out -----------------------------------

****
*   A68 - MC68000 ASSEMBLER   *
****

(C) COPYRIGHT 1985 ROBERT G. BROWN
ALL RIGHTS RESERVED

A68 VERSION 1.0 PLACED IN THE PUBLIC DOMAIN WITH THE PROVISION
THAT IT NOT BE SOLD FOR PROFIT WITHOUT THE AUTHOR'S CONSENT.

A68 VERSION 2.0 IS PLANNED AS A COMMERCIAL RELEASE IN MID DECEMBER.

CONTACT THE AUTHOR FOR FURTHUR INFO.

A68 TAKES A STANDARD 68000 ASSEMBLY LANGUAGE SOURCE FILE WITH THE
EXTENSION .A68 AND PRODUCES A GEMDOS .PRG FILE.

THE COMMAND LINE TAKES THE FORM
A68 filename

THE SOURCE FILE SHOULD CONTAIN STANDARD 68000 ASSEMBLY LANGUAGE
AS DESCRIBED IN THE M68000 PROGRAMMER'S REFERENCE MANUAL.

EACH LINE TAKES THE FORM:
[label] opcode[.ext] [source],[destination] [comments] or
*[comments]

LABELS - must start in the first column with a letter. They are
valid to 6 characters and contain letters and digits. Lower case
letters are converted to upper case by a68. A label must be
follow by a white space character (TAB or SPACE).

COMMENT LINES - are indicated by a * in the first column.

OPCODE - must be preceded by white space. The ext is .b for byte
.w for word and .l for longword. If left out .w is assumed. The
branch instructions use .b and .w for short and long branch.

OPERANDS - must be prceded by white space and separated by a
comma. The addressing modes follow the standard as follows:

SP is not accepted in place of A7 or a7.

The absolute short addressing mode is not supported by GEMDOS.
Absolute long is assumed as the default unless .w is used as the extension.

The address register with displacement (with or without an index)
mode is treated as follows:
     d(An)   d is treate as an absolute displacement.

The program counter with displacement (with or without an index)
mode is treated as follows:
     d(PC)   d is treated as location to which a displacement
is calculated.

For the displacement with index modes the length of the index
must be specified by the .w or .l extension.

# indicates immediate data

$ indicates hex (i.e. #$ff is immediate data 255).

Only simple expressions are accepted by version 1.0. (no + - etc.)

THE FOLLOWING PSEUDO-OPS ARE SUPPORTED:

EQU
label EQU value
use the EQU to reference absolute memory locations. The locations
referenced by a EQU are not relocated by GEMDOS.

ORG
 ORG value
use only as the first opcode in a file to create an absolute file
without the GEMDOS relocation information.

DC.[ext]
 DC.B 'string',$hexvalue,decimalvalue etc.
defines constants of lenght .ext. Moves to next even address
after DC.B.

DS.[ext]
 DS.l value
reserves value number of locations of length .ext.

DCB.[ext]
 DCB.W count,value
defines constant value count number of times.

A68 ERROR MESSAGES ARE REPORTED AS THE SOURCE CODE IS DISPLAYED
ON THE CONSOLE IMMEDIATELY AFTER THE ERROR IN THE FORM <**En**>.

1 - Illegal opcode
2 - Duplicate label
3 - undefined label
4 - illegal operand
5 - illegal size
6 - branch out of range
7 - displacement out of range

THE SYMBOL TABLE IS LISTED AT THE CONCLUSION OF THE ASSEMBLY AND
A68 WAITS THE A SPACE BEFORE RETURNING.

IF YOU FIND A BUG PLEASE REPORT IT TO

BOB BROWN
53 CLIFF LANE
LEVITTOWN N.Y. 11756

I've had my ACTION! cart for about 6 months now. I can't compare it with
C65, having never used it. To my mind, however, ACTION! could be the very
best programming environment on the Atari. The editor is very convenient
to use. The compiler is super fast. Try compiling 300-500 lines of anything
on any machine as fast as ACTION! can (just a very few seconds) on the Atari.
Although I've never examined the machine code emitted by ACTION!, my programs
tend to run blindingly fast. I've written programs in ACTION! for which I would
previously have resorted to assembler. The documentation supplied is
excellent, and the syntax is easy to learn. The only feature that I can think
of which is present in C and missing in ACTION! is recursion.

C is a general purpose large language (relatively speaking, no flames please).
ACTION! is a tiny language, well designed for execution in a (specifically)
6502 processor environment. For my money, ACTION! is the best choice to most
completely exploit the Atari environment.

If anyone out there in net-land is interested we could try some benchmarks
comparing ACTION! with any other Atari (or other manufacturer) high or low
level language.

Did anybody notice how, in the 8 bit days, all the Atari nuts said "Yes,
the Apple II is a faster machine, but the Atari is better because it has
better sound and graphics"? Today, all the Atari nuts are saying, "Yes,
the Amiga has better sound and graphics, but the Atari is better because
it is a faster machine"!

Frankly, I want a fast machine with superior sound and graphics. The ST
isn't fast enough, and the Amiga's graphics/sound aren't good enough.

'nuff said about toy computers.

   ...and according to an eyewitness (moi). By the latest count, there are
about a dozen club members with expanded machines, evenly distributed
between 256K and 512K. I have the necessary parts (<$30), and am eagerly
awaiting the next hardware SIG meeting so somebody can hold my hand
through the soldering stage (I just program the darn things).
  Incidentally, the last meeting was prefaced by a bouncing ball demo--
on an 800! It *was* a bit slower, but those buying certain nameless machines
based on that ubiquitous demo might want to consider spending $1-2K less for
the 8-bitter (:-).

   I've been meaning to post something about the updated BYTE board for the
last week. Since you got the scoop, I'll just add the following tidbit--
Mr. Buchholz saw a copy of the MAAUG newsletter recently, and wrote a letter
to our group. He said that he had succumbed to pressure to improve his
circuit (and sent us his result). He noted that the two were functionally
identical, but admitted to liking ours a bit better. He further stated
that he dislikes the "Rambo" name (I concur, though I approve of the
"Terminator" designation), and expressed his disappointment in not being
credited in the original articles (I think BYTE was mentioned, but not

Mr. Buchholz personally). Oh well.

    Some of you may recall some postings about cheap modems a while back, so heres a followup for all of you waiting with baited breath.... I ordered the Atari 830 and telelink cartridge from Atari for $25. It arrived a few days ago, and I've tested it with an Atari and 850 interface, and a normal terminal--it works as advertised. 300 baud is kind of slow, but for the price, I'm not one to complain.
    About the modem: it's acoustic, 300 baud, brainless (you have to set switches for originate/answer, full and half duplex), has it's own power supply, and comes with a cable to connect the rs232 on the modem to the serial on an 850. The rs232 must be normal because I used a HP plotter cable to connect it to a wyse terminal, and had no problems. Rumor has it that the modem is a Novation in an Atari box.... I also got an hour of Compuserve, Dow Jones, and the Source free [doubt that I'll use them, though].
    I'm not sure if Atari still has any, but for the price, it would be worth finding out (if you need a modem, of course). There was an 3 page ad in Analog about 2 months back.
    Hope somebody has some use for this.... BTW, allow a few extra weeks for delivery--they said about 6, and it took 8.

Patrick Madden, at a dusty terminal in a dusty town in a dusty state....
     And now with a dusty modem.
!cmcl2!lanl!unmc!nmtvax!pickle | "And through the wire
!ucbvax!unmvax!nmtvax!pickle | I see your face."
PS: Thanx to Mr. Hartman for the modem tutorials, Fun Eddy for the 850 and manual, and Ray for the cable and implements of destruction.

>Although the Amiga can play pre-recorded or synthesized sound samples it
>does not have built-in user sampling.

No, but it was a factor. By the way, I *was* aware that it couldn't input
sample sound but can output before I bought the Amiga. Sorry if my
original article gave mis-impressions there. I kinda felt being able to
play the samples back is a good 80% of the job. After all, you can get
by only sampling the input at a fixed rate if you absolutely have to, and
don't have to do input so often that it even has to be done by every
machine, but you need lots of controls and parameters etc. for the output
side usually. (if you want to play Beethovens 9th in dog barks that is).

I was going to post these results last week but our phone lines
were down. I received 15 responses (I think I pulled a few in from
postings but I'm not sure. I know I didn't get everyone who posted
(but didn't mail)) There were 10 Yes and 5 No.

Nearly everyone had ideas for what the groups should be called. Here they are

old machines	st
net.micro.atari	net.micro.st (2 votes)
net.micro.atari.eightbit	net.micro.atari.st
	net.micro.atari.520st
	net.micro.atarist
net.micro.atari	net.micro.atari.st (2 votes, one with a no vote)
net.micro.atari.8bit	net.micro.atari.st

There was one vote that we split, but that the group for old machines NOT be
called net.micro.atari800

Most of the no votes said there was not enough traffic and the eight bit
group would go away. One suggested that everyone use keywords to describe
which machines their message is about.

I head from:
pyramid!csg
ames-vmsb.ARPA!nep.pgelhausen
apollo!johnf

Whats happening out there? I have received no ATARI mail for some time? Did
the list collapse due to the lack of a moderator? Or are people just taking
a holiday break? In the off chance that net.micro.atari is still in
existance, let me try to pass on some interesting tidbits I've come
across recently.

In the Sept. or October issue of BYTE, there was an article on CD ROMS. The
article mentioned that the ST was the only ccomputer planing direct support for
such a device. They also talked about the potentials of this storage medium.
They mentioned a company that has a CD ROM with an IBM PC/xx interface (whof
course) and they had some encyclopedia on disk. (world book, I think) They
reiewer used it on his pc with software, and said he was able to do things like
have it search for all references to "COMPUTER". Such a search (of an entire
encyclopedia!!) took a very short time (< 1 min.). Also, this encyclopedia
took up only 2/3 of the disk space, and they plan a future version with
a complete dictionary and thesauris(sp?). I still have the article and can
clear up the exact specifics if anyone is interested. I forget if they were
planing to support the st or not.

In this months creative computing, in the "OUTPOST ATARI" column, there s

a good reviesw of the ST. The reviewer talks about the infamous problem with the ST chips coming lose in theeir sockets during transit.

An even more interesting article was in the N.Y. Times buisness section, on Monday 12/16/85. Ther is an article about the "face off" between ATARI and COMMODORE overthe ST and AMIGA. One interesting note from this article, is that there is much more software currently available for the ATARI than the AMIGA. I find this interesting, since this fall, one of the common arguments I heard on why you should not buy an ST, and should instead buy an AMIGA, was that the software situation for the AMIGA was and would be mushc better than for the ST.

Well, I hope this doesn't just bounce back to me with a "USER ID UNKNOWN TO HOST" or something like that. Ignore the typo's, I'm to lazy to correct them.

Keywords: printer basic dev kit
Summary: printers, basic, dev kit etc.

++++++++what is a line eater??!++++++++

     On the subject of printers, the Panasonic 1091 works really very well
with the ST, and seems to be somewhat better and cheaper than the Epson printers
usually recommended.
     The basic interpreter seems to arrive very slowly because Atari ran
out of them, or so they told me on the phone. Perhaps they've paused to
take out some of the very numerous bugs. Richard Frick said, when I asked
him about bugs, straightaway that the basic was very embarassing. He must

have been having a lot of people telling him about such things. Eg, hex$ of anything but an explicit number gives the string "50". But it's not too bad for wiling away the hours waiting for the development kit. They said the basic was being sent out 4 to 6 weeks late. But that is exceeded in my case.

Anyway, what I wanted to say about the developer's kit has now been saidby someone: that is, that it costs an extra 21 dollars for ship/hand, above the 300 for the kit itself.

Does anyone know how to get a full screen dump on the printer? I guess it's probably not so simple. But what would be very nice is a program to print out summaries of disk contents, like a program advertised at an excessive $50 for the Mac.

And finally, while waiting for my dev kit, I am just dying to know how the basic interp opens files and sends data to a disk or printer. I'm writing a disassembler in basic, and it would be nice to send stuff to the printer. Especially I'd like to use all the things my printer can do without going through someone else's software.

And in conclusion, I approve of comparisons of At vs Am in this newsgroup. It's a darn sight better than reading some of the biased and incompetent stuff that comes out in magazines. And in net.micro.atari, the few gems of wisdom easily compensate for the dribble (including the present note).

So long.

Alan Kennington.

The programmers here at Unit 36 Research have discovered a cute little bug in the DRI C compiler/assembler (for this is probably best considered an assembler bug). If one writes the code

```
a = array[i = 0];
```

where "i" is an int, the compiler will set up the zero value in a register to perform the array access. In order to do this it writes a "clr a0". The assembler turns this into a "suba.w a0,a0" instruction which will not actually

clear the address register. This instruction sign extends the lower word of the address register and then subtracts that value (using 32 bit arithmetic) from the original value. This leaves garbage in the upper 16 bits of the address register. If the compiler then uses that value as a longword: kaboom! It really needs to generate the long version of the instruction. Moving the index initialization out of the subscript cures the problem. We discovered this while writing a memory test program for the wonderful, sexy new .5 megabytes we have installed in the ST.

Thank you Bob Burch for the informative review of the 256K upgrades
available for the 800XL. Let me just add a couple of notes:

1) I did not develop the 256KXL but am acting as a distributor for
Newell Industries.

2) The 256KXL comes with MYDOS 4.0 which does support a ramdisk in
several different configurations. Also, OMNIVIEW256 has resident
ramdisk handlers which allow you to use the ramdisk in many environments.

What a relief that all the upgrades appear to address the extra memory
in the same way! Have we stumbled upon a standard? By the way, the 256KXL
does have a switch option to replace the original function of bit 5.
With this switch you can tell ANTIC to follow banked memory or stay
in main memory when banking occurs. We needed this mod to be compatible
with TYPESETTER by XLENT Software.

As I continue to moderate INFO-ATARI I learn all sorts of interesting

things. But I also need some help in bringing the records up to date. Following is the list I have inferred of where INFO-ATARI is redistributed:

```
!BBN! INFO-ATARI@BBN-UNIX,-
!BERKELEY! post-info-atari@BERKELEY,-
 "ihnp4!garfield!info-atari"@BERKELEY,-
!BRL! info-atari@BRL,genesis@BRL-BMD,-
!CIT! info-atari-users@CIT-HAMLET,-
!ECL! LOCAL-INFO-ATARI@USC-ECL,-
!MIT! BbInfo-Atari@MIT-XX,BB-INFO-ATARI@MIT-CLS,-
 Info-Atari%Wayne-MTS%UMich-MTS.Mailnet@MIT-MULTICS,-
!NRL! info-atari@nrl-css,-
!RICE! info-atari@rice,-
!SRI! INFO-ATARI@SRI-SPAM,TYSON@SRI-AI,-
 SHERWOOD@SRI-NIC,BBOARD-INFO-ATARI@SRI-CSL,-
!UBC! info-atari%ubc@CSNET-RELAY,-
!UTAH! UTAH-INFO-ATARI@UTAH-20,-
```

But I don't have addresses for the moderators of all these; I have the following:

```
!RICE! salex@rice,-
!UMASS! salamir%umass.bitnet@wiscvm,-
!BBN! knintzel@bbn-unix, postmaster@bbn-unix,-
!SRI-CSL! Geoff@SRI-CSL,-
!nrl-css! mullen@nrl-css
```

I would appreciate additions and corrections to this list. Among other possibilities, all moderators would need to coordinate splitting into two lists such as INFO-ATARI8 and INFO-ATARI16. On that subject, would the person conducting a poll please contact me.

Gee, I guess that makes you an authority on the subject (unlike those
of us who actually OWN an ST or Amiga :-)

>   ...The Amiga is a better computer, flat out,
>and it also costs twice as much. Which is better for the money?
>I don't know...

I'm sure you don't (make up your mind!)

>   ...I am tired of hearing atari salesmen, and atari

>owners, blabbing that the ST is "the same thing as an Amiga". That
>quote came directly from an atari salesman.

We all know how much knowledge salesmen possess (I base all of my
buying decisions on what they don't know :-). Seriously, I own an ST
(not a "520st") and am probably going to buy an amiga (Amiga :-)
sometime in the future. I, for one, do not believe that the two
computers are "the same thing". However, I do believe that if people
can stop arguing about which machine is better, then we might be able
to help both machines find strong positions in the (presently boring) PC
marketplace. Buy an Amiga or ST and write some software!

I don't know about the extra memory for ST BASIC, but I do know that
the upper 32K of the TPA (Transient Program Area) is reserved for
display memory.

how do you explain the much better drystone results of the ST?
(the compiler can not be the only thing responsible)

A *BIG* point about the ST is that 640 x 400, non-interlaced monochrome creates
a very good looking window environment that the AMIGA cannot match.

I do not think that your argument here is complete. It seems that I could argue
similarly in favor of the ST.

Hi.

This is my first attempt at participating in this info service. I
Hope someone confirms receiving this.

I am a new Atari 800XL owner. Here in Israel, the 520ST hasn't been
released, so all I know about the Amiga and the 520ST is what I read
in some magazines and on this forum (???).

I once read in CREATIVE COMPUTING (I think) something about a chip
called AMY which supposedly has 10.75 octave range and 8 voices. It =
was supposed to be offered in a computer called the 600 XEM, though
I've heard no further news on this computer. Does anyone know if it
is going to be produced? IF the AMY chip is still alive and well?
If it will be released in a cartridge for use in XL machines?

Also, today I was in Tel Aviv searching computer stores for answers
to an interesting question concerning MICROSOFT BASIC II.

It supposedly comes with a book, a cartridge, and an extension diskette.
the cartridge has 16K of memory, while the diskette carries 3.5K. I have
a diskette which, I was told, has ALL Of MICROSOFT BASIC II on it.

I don't understand what is going on here. Why didn't ATARI release
the whole package on a diskette? Was this to prevent copying? Can
MICROSOFT BASIC II work totally on diskette? The only OTHER explanation
I can think of is that the 3 1/2 K extension diskette is supposed to be
copied as a set of file management programs (like DOS and AUTORUN etc.)
But again. I DO NOT KNOW, and no one here can seem to tell me. I hope
this isn't too terribly amateur for you folks.

Also, is MICROSOFTs flight simulator also called SUBLOGIC?? I've never
seen one advertised by microsoft, just by sublogic.

Now for a few comments.

I've been reading with interest the advertisements and debates about
three hot computers: Amiga, 520ST and MACintosh.

If Amiga is indeed twice the price of the 520ST, then I really don't
think that the extra money spent is WELL spent, considering the 520ST's
characteristics, which seem to rival, if not top, those of the Amiga.
As for the Mac, we are dealing with a super-Atari for 1/4th the price
of a Mac, to which the only disadvantage seems to be a lack of software,
and I'm always weary of PROMISES by software companies to develop software.
I'm still waiting for PASCAL for the Atari, promised years ago, but never

delivered (to my knowledge).

But then again, if any new computer has to have thousands of programs ready to run upon its release, then there will never be another successful computer breakthrough, because people want software FAST!

And in closing my LONG first entry to this thing, let me add that its been my experience that Man is usually loyal to three things, in this order:

1) His religion
2) His country
3) His computer

so you'll never meet an objective computer owner...

Re: "... I want a fast machine with superior sound and graphics. ...."

Same here! The question is what is the required resolution. The Xerox workstations has superior (black and white) graphics at about 80 dots/in. The Apple Macintosh also displays near that resolution. Therefore 640x400 on a 8"x5" (about 10" diagonal) monitor would look nice if it's non-interlaced. I am disappointed that Amiga comes so close yet still misses the mark.

I hate to think that it is really me that is involved in a ST vs Amiga war
but I have to take exception to this article. There are a lot of very cute
and superior things about the Amiga. There are also undeniably superior
features that the ST can boast. I am incredulous that the Usenet has spawned
so many articles devoid of any reasoning and filled with such misguided
emotion. If I can get a computer that has a 68000, 640 x 400 non-interlaced
graphics, and that runs code faster than than any other personal computer
(including the amiga -see the drystones) And I can get it for $600
(yes it has been discounted that low) I feel that that is a far superior
computer *FOR ME*. I however do not really need the color, sound capabilities,

bus expansion, animation, and hope to use OS-9. The type of reasoning that is being displayed in some of these articles seems more appropriate while discussing football teams at one's favorite bar.

After reading the above article, I downloaded the revised procedure from Compu Serve. I have had the upgrade for about 3 months, and has worked without a flaw. I would have probably added the proms without the resistors. Thanks to Mr. Turner for the warning.
Here is a copy of the revised procedure:

NOTE: This is an REVISED,TESTED version of the original text downloaded from CompuServe. December 6, 1985

(This was REVISED AND TESTED by an annonymous engineer on Atari's developement staff. The addition of the resistors should provide a long life to your machine, but the warning below is STILL IN EFFECT. This is not an official sanction of the modification. USE WITH CARE!!!)

Here's the 1 Meg upgrade directions:

I have brought this over un-editted from the arpanet info-st mailing list. I TAKE NO RESPONSIBILITY FOR ITS CONTENT OR ACCURACY. I HAVE NOT TRIED THIS MODIFICATION ON MY OWN ST AS YET. I AM PASSING THIS ALONG TO THOSE WHO DO WISH TO TRY IT. FOLLOW THE DIRECTIONS AT YOUR OWN RISK.
--Dwight McKay (75776,1521)

From: gert@pescadero

WARNING: This is a hardware modification that will void the warranty of your 520ST. If you do not have the appropriate tools or experience you have a substantial chance of ruining your 520ST. Proceed at your own risk! This modification has been in my 520ST without any problems for 6 days now. However, I have (of course) not checked with knowledgable sources at Atari to verify if this modification endangers the long term machine reliability and/or software compatibility (I suspect it may endanger their software compatibility if enough of us do it!)

Tools & components needed :

16 256k * 1 RAM chips, 150 ns access time type, e. g. NEC 41256C-15 (avilable at e. g. Fry's Electronics, Sunnyvale, CA for $2.77 each)

A good quality, preferrably temperature controlled soldering iron, with a minature tip (tip should be narrow enough to avoid touching 2 I. C. pins at the same time). E. g. Weller type soldering station.

Good quality resin core solder (thin).

Approximately 4 foot of #24 AWG insulated wire and a good stripper for it and 2 feet of #22 AWG solid tinned copper

bus wire. You will have to route 3 wires over a sequence if I.C. pins.

Desoldering wick and solder suction tool.

Philips type screwdriver (for opening your ST), tweezers, pliers, etc.

A steady hand and self-confidence.

Explaination of the modification :

(Please read the rest of this document before starting. It may save you time and an 520ST)

The current memory inside the 530ST consists of 16 256K*1 RAM chips. Address (A0..A8) lines are common to all those chips. The WriteEnable line is also common to all chips. Data (in and out) lines are of course individual. The RAS (row-address strobe) line is common to all chips. The 8 chis foring the high order byte group have one common CAS line, and the 8 forming the low order byte group have one common CAS line (CAS is used as enable for write operations, such that WriteEnable can be common to both groups). The high order group from MSB to LSB consists of U45, 44, 43, 42, 38, 34, 33, 32. The low order group of U30, 29, 28, 25, 24, 28, 27, 26. Note that all chips are adjacent, though the numbering has gaps. RAS0, CAS0H, and CAS0L are supplied from U1 pin 8,6 and 7 respectively (The 0 indicates bank 0)

Bank 1 that you are going to build in will be "piggy-backed" on top of the current chips, where all pins of the new chips EXCEPT RAS (pin 4) and CAS (pin 15) are soldered to the old chips equivalent pins. Thus they will end up sharing addresses, data, WriteEnable and power and ground with the existing chips.

All RAS pis of the new chips are wired together and will be supplied with the "RAS1" signal generated on pin 18 of U15 (the memory controller, marked 3H-2119C or so). The CAS pins of the 8 new high order byte chips (on top of U45..U32) are wired together and supplied from the "CAS1H" signal generated on pin 22 of U15. Analogously, the CAS pins of the new U30 to U16 are wired together and supplied with "CAS1L" from pin 21 of U15.

How to go about it:

Step 1: Open up your 520ST, pull off the keyboard connector and remove the main circuit card from its top and bottom shielding. Make sure to remember which screws go where and note the keyboard connector orientation.

Step 2: Desolder all of the capacitors adjacent to the existing RAM chips. (DO NOT SKIP THIS STEP. You'll lose time if you do, and worse, the modification will no be reliable since you can't solder pins obstructed by the capacitors reliably (if at all)). To desolder them, I found it easiest to heat the island on the non component side, and bend the wires straight. After doing that or each capacitor, turn over to the component side and heat the islands wile pulling the capacitor out with the tweezers.

Step 3: Open up the holes of all the desoldered capacitors, using a combiation of de-soldering wick and suction tool. Do this from the non component side. If certain holes are difficult to open up, you may want to use a wood splinter. (push it through while heating). Be carefull to remove all solder debris!! THE REASON for opening the holes NOW is that they will be less accessible once you've done the other steps! Patience is a virtue.

(NOTE: Step 2 & 3 are the only ones that may damage your ST PC board. Be sure not to use excessive force while pullling out the capacitors. If you damage your PC board anyway, cure the problem now and not later).

Step 4: In this step we will piggyback the new RAM's on top of the old oes. Be sure to connect all pins except pin 4 (RAS) and 15 (CAS). The best way to go about this is to do chip by chip. First, bend the pins of the new RAM's suchthat hey are perpendicular to the package (instead of having slightly spread "cowboy legs"). Use pliers to bend pin 4 and 15 such that the legs are 180 degrees from their normal position, so they stick up in the air above the plane of the top surface of the chips. Don't make an absolute sharp 180 degree bend since some manufacturers' pins may snap off. Leave a little curve in the leg, but insure that is above the plane of the top surface of the chip.

Using #22 AWG to #16 AWG tinned solid copper wire you will form three buses along the top surface of the new d-rams. Cut a #22 AWG solid copper wire the length of the 16 d-rams on the PCB. The RAS bus is formed by soldering all the pin 4's of the new d-rams to the solid copper wire. The bus wire must be seated against the top surface of the new d-rams without a gap. This insures clearance between the top shield and the pins of the d-rams.

After soldering all 16 d-rams to the bus clip off any portion of the pins that extend above the top of the bus wire. Now cut a #22 AWG solid copper wire the length of the 16 d-rams. Place the bus wire along the top surface of the new d-rams in contact with all the pin 15's of the new d-rams. Solder every pin 15 to this bus and as above insure that the wire is seated solidly against the top surface of

the new d-rams. Cut off all excess pin length sticking up above the top of the bus wire. Using diagonal cutters remove the section of the bus connecting the new U30 pin 15 to the new U32 pin 15. This divides the bus in half with the new U16, 17, 18, 24, 28, 29 having a common pin 15. The new U32, 33, 34, 38, 42, 43, 44, 45 now have a common pin 15, seperated from the other common bus.

(NOTE: until step 6 is finished, do no in any way apply power to your ST. This intermediate state of affairs will damage your memory chips!!)

Step 5: Remount all the desoldered capacitors. Bend the pins like they were before resoldering, suchthat they will not touch the lower shielding. Solder from the non component side.

Step 6: Orient the 520ST PCB so that you are looking at the solder side of the PCB (non-component side), with the row of d-rams nearest you. Find the double square pattern of pads at the 68-pin socket of the memory controller, U15 (3H2119). The following is a guide to locating the six memory controller pins necessary to complete the wiring. The socket is numbered conterclockwise, starting with pin 1, the square pad (look closely) in the middle of the bottom outside row. The sequence, moving counterclockwise from pin 1, first on the outside square ONLY: (NOTE: the sequence ")(" means to make a 90-degree turn counterclockwise, i.e. around the corner)

1,3,5,7,9)(10,12,14,16,18,20,22,24,26)(27,29,31,33,35,37,39,41,43)(44,46,48,50,52,54,56,58,60)(61,63,65,67

The sequence, moving counterclockwise along the inside square only, and starting with the left side of the bottom row:

(62,64,66,68,2,4,6,8)(11,13,15,17,19,21,23,25)(28,30,32,34,36,38,40,42)(45,47,49,51,53,55,57,59)

Six 68-ohm 1/4W plus/minus 10% carbon film resistors must be added when adding memory. These series terminating resistors minimize undershoot which may damage BOTH BANKS of d-rams if omitted. Solder a 68-ohm resistor to pin 18 of U15, RAS1. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm resistor to the pin 4 bus (RAS) of all the new d-rams. that is the new U16, 17, 18, 24, 25, 28, 29, 30, 32, 33, 34, 38, 42, 43, 44, and 45.

Solder a 68-ohm resistor to pin 22 of U15, CASH1. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm resistor to pin 15 bus (CAS) of the new U45,44,43,42,38,34,33,32.

Solder a 68-ohm resistor to pin 21 of U15, CASIL. Solder a #24 AWG stranded wire from the remaining end of the 68-ohm resistor to pin 15 bus (CAS) of the new U30, 29,28,25,24,18,17,16.

For best results in all three cases above solder the wires coming from the resistors to the middle of the three bus wires in a "T" fashion rather than at one end of the buses.

Use a continuity tester to find the following three traces -- do not depend on visual inspection. Now install three 68-ohm series terminating resistors in the original 512K bank of ram. Be very careful while soldering to these narrow traces, since excessive heat can easily lift a trace from the board. Use an Exacto knife to gently remove solder mask from traces.

Cut the trace leading from pin 8, RAS0, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Cut the trace leading from pin 6, CAS0H, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Cut the trace leading from pin 7, CAS0L, of U15 near U15. Solder a 68-ohm resistor in series with the trace.

Step 7: Sit back. Use Brain. Do you feel confident about the quality of your work? No mistakes? Check evrything once again if you are but a little uncertain. Applying power with errors might make your ST into a decorative, nonfunctional piece of art. OK. Either rebuild your ST into its shielding and cabinet, or put it onto a surface clear of wires and solder remians and connect it to monitor, disk and supply. Boot it.

It it boots, you're probably there. Test if the new memory works by looking at the phystop variable ($42E) with SID if you have the developer stuff. It should read $100000 (1M hex). Also note that memcntlr ($424) now holds 5 instead of 4, and that v_bas_ad ($44E) now holds $F80000 (screen bitmap origin). If you don't have the developer stuff, try a single drive copy and check that you get the whole disk in one buffer instead of two.

If the new memory does not seem to exist, use SID to deposit and retrieve words on locations $80000 and up (1/2 Meg hex). If bit errors occur, the ST bootROM did not detect the extension (it checks all bits of 512 locations by testing a psedo random sequence, before accepting a memory bank). Try to pin point the faulty chip(s) and remove the error.

If it doesn't boot, you're in trouble. I'm sorry. It is

difficult to give hints on what to do here. So many possibilities. Desoldering the new chips probably won't work (if the old ones were functional, the ST would still boot). Check for hidden short:circuit on the RAM pins. May also be that you have a flaky new pin connection.

That's all there is...

Hi.

This is my first attempt at participating in this info service. I Hope someone confirms receiving this.

I am a new Atari 800XL owner. Here in Israel, the 520ST hasn't been released, so all I know about the Amiga and the 520ST is what I read in some magazines and on this forum (???).

I once read in CREATIVE COMPUTING (I think) something about a chip called AMY which supposedly has 10.75 octave range and 8 voices. It = was supposed to be offered in a computer called the 600 XEM, though I've heard no further news on this computer. Does anyone know if it is going to be produced? IF the AMY chip is still alive and well?

If it will be released in a cartridge for use in XL machines?

Also, today I was in Tel Aviv searching computer stores for answers
to an interesting question concerning MICROSOFT BASIC II.

It supposedly comes with a book, a cartridge, and an extension diskette.
the cartridge has 16K of memory, while the diskette carries 3.5K. I have
a diskette which, I was told, has ALL Of MICROSOFT BASIC II on it.

I don't understand what is going on here. Why didn't ATARI release
the whole package on a diskette? Was this to prevent copying? Can
MICROSOFT BASIC II work totally on diskette? The only OTHER explanation
I can think of is that the 3 1/2 K extension diskette is supposed to be
copied as a set of file management programs (like DOS and AUTORUN etc.)
But again. I DO NOT KNOW, and no one here can seem to tell me. I hope
this isn't too terribly amateur for you folks.

Also, is MICROSOFTs flight simulator also called SUBLOGIC?? I've never
seen one advertised by microsoft, just by sublogic.

Now for a few comments.

I've been reading with interest the advertisements and debates about
three hot computers: Amiga, 520ST and MACintosh.

If Amiga is indeed twice the price of the 520ST, then I really don't
think that the extra money spent is WELL spent, considering the 520ST's
characteristics, which seem to rival, if not top, those of the Amiga.
As for the Mac, we are dealing with a super-Atari for 1/4th the price
of a Mac, to which the only disadvantage seems to be a lack of software,
and I'm always weary of PROMISES by software companies to develop software.
I'm still waiting for PASCAL for the Atari, promised years ago, but never
delivered (to my knowledge).

But then again, if any new computer has to have thousands of programs
ready to run upon its release, then there will never be another successful
computer breakthrough, because people want software FAST!

And in closing my LONG first entry to this thing, let me add that its
been my experience that Man is usually loyal to three things, in this
order:

1) His religion
2) His country
3) His computer

so you'll never meet an objective computer owner...

Randy Magruder

According to the January 1985 issue of ANTIC, there have been some changes made on CompuServe. SIG*Atari is now split into three special interest groups--plus the ANTIC ONLINE electronic magazine. There is a SIG for 8-bit Atari computer owners, a 16-bit SIG for Atari ST users and a software developers forum. Each SIG has as much online space as the original SIG*Atari.

Half of the developers forum will be open to the public and will be a up-to-the minute source of information on new products. The other half will be reserved for professional software developers, authors and retailers. A special section within the developers forum will provide technical support for the professional software tools published by the ANTIC Catalog.

The ANTIC ONLINE section has been enhanced and features the Professional GEM Helpline with a twice-monthly column for Atari ST developers by Tim Oren, who designed and implemented the GEM Resource Construction Set as well as other parts of the GEM Programmer's Toolkit. He is a former member of the GEM programming team at Digital Research, Inc.

Oren's ANTIC ONLINE column will initially be geared to people who have both a knowledge of the C programming language and a copy of Atari's ST Programmers Toolkit with documentation. "Every two weeks, Professional GEM Helpline demonstrates amazing new tricks while guiding ST developers past pitfalls and strange bugs that lurk for the unwary." (that's a quote directly from ANTIC).

They also mentioned that they will no longer be uploading ANTIC ONLINE or SIG*Atari onto the Delphi service, so it looks like CompuServe is still the best place for serious Atari owners and developers to have a subscription.

I am looking for information on the file format used by Micro-Illustrator. I have the cartridge for my 800 that uses the PowerPad touch tablet as the input device, and also have the public-domain Paint! program that uses a joystick. I would like to be able to convert pictures from one format to the other and also do things like add text to the pictures, and do some kind of screen dump to printer program.

The Paint! program seems to store in a straight forward screen dump format with some bytes for preserving the screen color registers tacked on. The Micro-Illustrator, however, must be using some kind of compression algorithm, as the file size varies with the amount of detail on the screen. Can anyone out in Netland provide the details of the format?

The original Microsoft BASIC was on diskette. A later version was released on cartridge, with a diskette containing a few less frequently used functions which wouldn't fit into 16KB (the cartridge capacity). Advantages of the cart, aside from being more difficult to copy, were higher reliability and much faster startup.

> I don't understand what is going on here. Why didn't ATARI release the whole package on a diskette? Was this to prevent copying? Can MICROSOFT BASIC II work totally on diskette? The only OTHER explanation I can think of is that the 3 1/2 K extension diskette is supposed to be copied as a set of file management programs (like DOS and AUTORUN etc.) But again. I DO NOT KNOW, and no one here can seem to tell me. I hope this isn't too terribly amateur for you folks.
>
> Also, is MICROSOFTs flight simulator also called SUBLOGIC?? I've never seen one advertised by microsoft, just by sublogic.

The Microsoft Flight Simulator is for the IBM PC. It was written by Bruce Artwick of subLogic, who markets the other versions (Atari, Apple, Commode) directly through subLogic.

> Now for a few comments.
>
> I've been reading with interest the advertisements and debates about three hot computers: Amiga, 520ST and MACintosh.
>
> If Amiga is indeed twice the price of the 520ST, then I really don't think that the extra money spent is WELL spent, considering the 520ST's characteristics, which seem to rival, if not top, those of the Amiga. As for the Mac, we are dealing with a super-Atari for 1/4th the price of a Mac, to which the only disadvantage seems to be a lack of software, and I'm always weary of PROMISES by software companies to develop software. I'm still waiting for PASCAL for the Atari, promised years ago, but never delivered (to my knowledge).

To avoid excess flamage on this subject, let's just say that the extra features may not mean much to YOU, but that other users may have very different sets of criteria for judging the systems. Others may question the thousands I've put into my audio/video equipment. Personally, I think it was money well spent.

BTW, Pascal WAS shipped for the 8 bit Atari. It was sold through the Atari Program Exchange. Atari didn't make a big deal about it because it was so big and slow and required two disk drives to do much of anything.

I have owned an Atari 800 four 4 years and I have never heard anyone say that the Apple II was faster than the Atari. (True, disk access is faster). If you think the new ST and Amiga are toys then you are in the minority. Both computers are more powerful and elegant than the IBM PC. I guess the computer elitists will look down their noises at any computer which is priced to be affordable by the average consumer. As for me, I welcome the rest of the world into the computer age.

John

Thank you very much for replying to my questions. Since I believe that
other potential buyers might be intersted in this discussion, I am
following up to the net.

||(b) the AMIGA has better special-purpose graphics capabilities than the
|| ST, but at the expense of main CPU speed.
|
| Absolutely false. The graphics capability is achieved with co-processors
| which tend to let the CPU run at full speed much more often than if the
| CPU were responsible for display updates. Note that the coprocessors
| also allow I/O to proceed independently of the CPU, as well.

Let me state the question more precisely: is there any difference in
speed between the ST and the AMIGA when either machine is just
displaying a bit image, without any active painting or sound production?

||(c) the AMIGA graphics is said to be not usable at a
|| resolution of 640x400 for text or serious graphics applications.
|
| Probably true, but only until monitors become available that address
| the special problems with 640 X 400 mode (using color - there are mono-
| chrome monitors which will work quite well at 640 X 400, and the ST, as I
| understand it, forces monochrome at that resolution anyway)

Again, let me state the question more precisely. I thought the problem
with the AMIGA 640x400 display is that it is interlaced, and that therefore
every line only gets re-freshed at a rate of 30Hz. The only way to
'fix' this would be to use high-persistence phosphors, clearly not
a desirable solution. Is this true? How does the ST deal with
this problem?

And there are a few more questions that came to my mind in the meantime:
-- are there MacWrite type word processors available for either machine?
   How easy are they to adapt to a specific printer?
-- what terminal emulators are available for the two machines? Are
   they reliable? What protocols do they support for file transfer?
-- what graphics design programs (in the style of MacDraw) are available
   for either machine? How usable are they?
-- what is the scoop on the difference between disk capacity and disk
   speed between the ST and the AMIGA?
-- are there versions of either machine which will work with BOTH
   120/220V 50/60Hz?

                              Thanks,
                              Thomas.

    ================

Ha! I can tell you that, as a former high-strung prima donna myself.
Most of the coin-op development (the only part of Atari still owned by
Warner Communications, last I heard) is done on Vaxen under VMS, using
old cross-assemblers written in 11 code, which run in 11 emulation
mode, and run very slowly. Doing real work on the Vaxen takes a certain
stamina, not to mention tolerance for teeth-gnashing.

Hello World. I would like to ask that those of you who post these
ST vs Amiga comparisons to back them up with facts and don't cross
post the articles to both newsgroups. I'm sure that those who are
interested in both machines subscribe to both groups so just post
the ones that say 'the ST is better' in this group and the 'Amiga
is better' ones in the Amiga newsgroup. Sorry for this interuption
in news reading, we now return you to the regular promgramming.

Maybe we can get of the Amiga vs ST bit and switch over to
"Does UNIX really need MMU: discussion.

I couldn't help but notice that there have been multiple
postings from Dublin, Ireland about how the ST has no mmu, never will
and therefore can't run UNIX. Memory manegement is a luxury,

not a necessity. I've seen UNIX evolve since its early days,
when you could sit down and pretty much see what's where in one
weekend if you had the sources. Unix has since changed, but neither
then, nor now do I see why MMU is necessary to running
unix. I do, of course, assume that the environment is fiendly,
and security is not an issue, moreover that programs don't randomly
walk all over memory. (this latter may a very strong constraint, seeing some
code that is floating around).

So my version of the bard's song is:

THE ST HAS NO MMU
SO WHAT?
IT THEREFORE MAY OR MAY NOT RUN UNIX ....:-)

(If you had seen earlier postings, it would help)

First off, i am in *no* way connected with the OSS company and
i am just posting this because there is a general interest in new
Atari 520ST software....(etc)....

Two pieces of software are being released by OSS in late December:

PASCAL -(with extensions into GEM and otherwise) "...strings,

...debugging options, special code optimizer and easy to use
GEM support. It includes "compiler,linker,libraries,editor,"
Suggested retail will be $89.95. (Not feeling well today, and
staying home with little else to do ...) i called OSS...the
person that answered seemed knowledgeable and appeared to have
a good feel for the C products out. (I forgot to ask about
floating point libraries, if someone else finds out...pleez post)
He mentioned that the compiler was now written in Pascal (itself)
and that the GEM support would "blow the doors off of the competition."
This reference was meant i think to convince me that they are taking
pains to provide better (or less cryptic) graphics functions. (libraries)

additionally OSS is releasing a GEMDOS(TOS) DiskKit to examine, repair,
and modify TOS diskettes.

------
ahhh....finally the real reason i called...OSS has announced that they
will release Prolog in March of '86 (they have or are announcing
availability of a Prolog for the Macintosh...this will be a port of the
Mac software).

Just in case anyone is interested their address is :

I was looking for a word processor for my ST today and came across one called
THE FINAL WORD. I was wondering if anyone has used it and what they think of
it. (It seemed as if it had been ported from another machine (the PC?))

This on seemed fairly expensive ($145) so how much better is it?

In addition, they were selling a VT100 emulator. It was called PC/Intercom.
Any information on this one?

My final question is about a public domain RAM disk. Where can I get one?

Thanks in advance,

Bart Atwell

i wouldn't bet my terminal too quickly, there WILL be a unix
available from Atari and it will be AT&T V7, but not for the ST. The
above reasons while not vital are critical enough to make it too
difficult to do. The Atari port will be for the TFM machine and your
timeframe is about right, nothing is set in concrete but it will be
a black box with a 68020 (i hope) or a 32032 in it and it will use
the ST as an intelligent front end, windowing terminal etc.

Summary: Microware's 68K C is $400.00

I have just learned that unlike their 6809 C Compiler, Microware is charging $400.00 for their 68K C compiler which runs under OS-9. There may be other C compilers available for OS-9 68K, but I don't know about them right now.

Cheers! -- Jim O.

<here, line eater .. nice line eater .. >

Potential scam here, folks.

I saw an ad in the NY Times this past Tues (12/17) from one Executive Photo on 31st St, Manhattan. In their computer section, they had the following entry: "Atari 520 ST $369.". I called their WATS number (800-223-7323), frankly assuming a typo for an intended price of $639, still an excellent discount on the B&W ST.

When I got through to them, they told me over the phone "That's the price for the CPU only, the package is $699."

Say WHAT?!?!?!

I called the distributor in Westchester county as shown in the recent ST ads and asked if the ST was available unbundled. The answer was that they had heard Atari was considering it, but not at the present. Okay, I called Atari in Sunnyvale. The person I got was 'puzzled'. They took the dealer's name & phone #, my name & address, and said they'd look into it.

If the manufacturer doesn't offer something unbundled, and the regional distributor doesn't distribute it unbundled, and NO ONE has ever advertised the item in unbundled form, what do you call an ad selling you a piece of an otherwise bundled system? I called Executive again to see if they were still holding to their line. They were. I called the NY state Atty General's office and have requested complaint forms be sent. I think false advertising charges are appropriate.

ANYONE else ever see ads for unbundled ST systems? I don't mean supplemental drives, etc. I mean an ad along the lines of 'CPU only $XXX, monitor $XXX, first disk $XXX'. If so, please let me know. Thanks.

Bob Halloran

Please state what machine you have converted to "One Meg" -- locally there
are now both 520ST's and 130XE's that have been converted to one meg. I
am interested in the 130XE conversion.

By the way, have heard via the grapevine that the 256XE is about to hit
the market place, anyone seen one yet? Why doesn't Atari just bite the
bullet and bring out the 1040XE? The "Super 520" (why not 1040ST?) is
now available in europe, why not in the good old USA?

Whoops! I should have said 260XE not 256XE. I do wish that Atari Corp.
would make up their mind as to how they are nomenclating their products.
The new 256ST has 512k memory. The super 520ST has 1 Meg memory. Why
not stay with what they started?

Granted, the graphics chips relieve the 68000 from dealing with the
display, as it must in the Mac, but the 68000 and the various co-processors
must still contend for access to memory. YES, I/O can proceed independently,

etc., but only ONE of the processors can use memory at a time. This
HAS to impact the throughput of the 68000.

BTW, the ST also has an I/O co-processor, so presence vs. non-presence
arguments in favor of the Amiga are inappropriate.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

The ST uses up to 6 27256 eproms.
The adress space for the EPROMS is 96k words on the ST so you
need 6 27256 to give you the full amount (3 sets of 32k x 16)

The 27256 eprom is organized as a 32k X 8 bit memory.
There fore you need 2 27256 to give you 32k words.
If you look inside the ST you will see six sockets
with roms in the first and third socket.
Also you can use 2 27128 or 2 2764 to give you 16k or 8k words
of memory.

>-- are there MacWrite type word processors available for either machine?
(Answeres given for Amiga computer, note my bias)

Textcraft is the only thing I am aware of. It is oriented toward "home"
or "new small business" use. On a 256k machine it can handle about 6-10
pages of text. One font in many styles (bold, italics,...) is supported.
>   How easy are they to adapt to a specific printer?
Trivial if you select one of the "standard" supported printers:
     Alphapro 101, Brother HR15xl, CBM MPS1000, Diablo (630, Advantage,
     C-150), Epson (fx series and JX80), HP laserjet (and plus),
     Okimate 20, Qume leterpro 20.
If you do not select any of the above you can select "generic".
NOTE: All "right-thinking" software uses standard Amiga (ISO, DEC, Amiga)
escape sequences to the PRT: device. If the attached printer can do the
requested operation the Amiga "translates" the command for the printer
and issues it. Printer independent software is a snap! (The "generic"
printer is assumed to have no features.)

>-- what terminal emulators are available for the two machines? Are
>   they reliable? What protocols do they support for file transfer?
Several available, see past postings. Companies posted include:
     Micro-Systems Software, IncModem7/Xmodem, XmodemCRC, and
       Hayes-Smartcomm file xfer protocols
     ELCom's ElTerm data communications package. both KERMIT and
       XMODEM built in. ansi terminal emulation
     Maxicorp, Maxicomm package.
     Commodore is marketing one also.
>-- what graphics design programs (in the style of MacDraw) are available
>   for either machine? How usable are they?
     Graphicraft (Commodore Amiga) and Delux Paint from Electronic arts.
     Both seen to have the limitation the the painting cannot exceed
     the size of the screen. EA supports 640x400 (interlaced).
     You may want/need more than 512k of RAM.

--BruceB
Disclaimer: I work for Commodore-Amiga. I have played with TextCraft and
Graphicraft alot, but not with Deluxe Paint or any of the Comm packages.
Everything above is, undoubtedly TM or Registered. I hope all of the
above companies prosper and continue to come out with new produces for
the Amiga.

I just installed CDY's 256K upgrade in my 800xl and am fairly pleased. All the XE versions of programs I've tried work fine (Synfile, Syncalc, Paper Clip, and Atari Writer+.) Using the Omniview OS I'm able to create and use a RAMdisk with DOS 2.0 (Other DOSes are better but the ability is still there).

I also installed CDY's Ramrodxl and Omniview. I'm glad I got the Ramrodxl, because some software refuses to boot with the omniview chip, for example: the XE version of paper clip, and electronic arts games. 80 columns, even using a good monitor, is hard to look at for long periods of time. I suppose that if I had a good monochrome monitor it would be much better.

The omniview OS is supposed to be super 400/800 compatable, it does boot MOST of the software that needed translation but, alas, Blue Max still won't boot (lucky for me I still have my trusty 800 :-)).

I am having some problems, and I'm not sure if they are due to my soldering or inherent in the upgrade. If anyone else has done the upgade I'd appreciate responses. Anyway, here's the quirks I see:

1. Booting the non-XE version of Paper Clip gives me the the same buffer space as if it was booted on a 48K machine (427 FREE) rather than the 800XL buffer size (785 FREE). I know, I should just use the XE version, but it still bugs me!

2. I sometimes have trouble booting another program, even doing a power off/on leaves me in a wierd state - the disk isn't accessed until I power the DISK off/on.

3. I sometimes get random garbage on the screen when I'm booting, the program seems to behave ok - just unsettling to watch.

And now for my wish list (are you listening David Young?):

1. I would like to be able to switch ramdisk drive numbers without resetting. It would be great for loading the back side of an Infocomm game into a ramdisk, booting the front, and then switching the ramdisk to drive 1 - playing Infocomm in RAM what a joy!

2. It would be nice to be able to have two single density ramdisks. Then (using the first request) you could load the Synapse novels and not GRIND your disks to death.

Disclaimer: My only connection with CDY is that I own a few of there
             products and they own some of my (as yet unearned) money (where
             would we be without plastic?)

Editorial, Infoworld Dec. 2 1985

...But opening new areas of computing or releasing floodgates of demand are not the only things that make a winner. Value, always an important consideration in the high-priced, high-tech world of microcomputers, represents the major criterion for two of our awards this year. Our Hardware Value of the Year goes to the Atari 520ST, a product whose makers pride themselves on providing quality

for a low price. Indeed, what last year was available only on machines costing $2,500 and up can now be had for less than $1,000. The power of a 68000 microprocessor, the ease of an icon-based graphic user interface, and the ability to do serious work is available for the cost of last year's toy. Atari 520ST, an amazine machine for the money.

Need I say more?

Aloha,
Jonathan Spangler

In article <284@yetti.UUCP> oz@yetti.UUCP (Ozan Yigit) writes:
>   Perhaps it is safe to say that some MAC programmers worry more
>   about how the program *looks* rather than what it *does*. SIGH.
>   And I thought the advancement of systems like MAC would clear

>   away all the interface blues, and let people concentrate more on
>   the *functionality*.

Almost any source I have seen has function mixed w/interface all over it.
Not just on the Mac -- look at Unix sources. It's possible to call
a separate module everytime you need to handle an exception, do i/o,
or whatever -- but very few people bother. (Quick, what was the last
major C program you wrote where every call to a routine from section III
of the manual was separate? No forks, etc.?)
     Sure, portability is desirable. But most people are aiming at a
specific target, and why should they make their code more complex and
fragile to support a machine they are not interested in?
     Something that escapes most mainframe-oriented people is that it is often
nearly impossible to get tech support (even manuals!) w/o buying software
to go with it. Even IF someone wanted to write for Apple's Toolbox,
Atari's Gem, and Amiga's Intuition interfaces, they'd face major problems
in finding out how to write/support software on a second and third machine.
This discussion is about what people do for *FREE*, after all.

Tired of paying ridiculous prices for cables for your PC at local computer
stores? I've found an excellent source I thought I'd pass on to you. Its
Jameco Electronics, 1355 Shoreway Road, Belmont CA 94002 (415) 592-8097.

Their shielded IBM to Centronics 8' printer cable (IBM-8PC) is only $17.95
(compared to $40-50 for the computer stores) and shielded 6' RS232 cables are
$10.75 (male-male, MMS-2206) and $10.95 (male-female, MFS-2206). I've seen
these cables priced between $35-$40 at the computer stores.

The cables seem very well made and should be quite durable. The only catch is
that Jameco has a $20 minimum order requirement.

Lines: 33

There's been discussion of 256K upgrades for 800XL's and 1200's, but some
of it misses the mark for those of us with "old" 800's. The real question
is how to get maximum advantage from memory upgrades. So far, I know
of five schemes for 64K+ memory expansions:

```
        Axlon ramdisk 128K     ... don't know how it works ...
        Atari 1200 (other XL?) extra 16K swapped with O.S., PORTB selected
        Mosiac Select          4K banks at $C000, non-PORTB select scheme
        Atari 130XE            16K banks at $4000, PORTB selected
        Byte's 800XL 256K "dog"  ??
```

The problem comes when you realized that NONE of these is standard. Yeah,
sure, Atari themselves came out with the XL's and the 130XE, but the two
aren't compatable and (worse) have little to no support from the O.S.
software.

So: how to get the best use out of add-on memory? Shall we take the
130XE as the new standard, and junk all of our old stuff? I know it's
a little late in the game to be talking about standardizing 800 add-ons,
but isn't there something we can do about it?

Now the suggestion (are you listening, C. Dave Young?): how about some
kind of software "standard" which would let you use the extra memory
regardless of what Atari it's on and how it got put there. Hide the
differences between the above systems in some sort of low-level
"extra memory" handler. Ramdisks address part of the problem, but
there are many applications for which you want memory, not emulated
disk files.

....anybody have some ideas about this?

Note: I am adding net.micro.{mac,amiga,atari} to this, because this article
is really about portability between the Mac, the ST, and the Amiga.

[I am >>]
In article <-13400@brl-tgr.UUCP> jon@brl-tgr.UUCP writes:
>>> [compaint that Mac programmers are not writting portable code.
     Mentions that other machines have windows besides the Mac]
>> Are you saying my Mac programs should easily port to the Amiga, the Atari
>> 520ST, the Sun , V8 Unix (if you have a BLIT), System V (if you have
>> a Teletype 5620), the IBM PC and Clones (with GEM), the AT&T PC7300,
>> and a few random Xerox machines? They all have windows.
>>
>   Are you saying you want to write different programs to accomplish the
>same thing on all these machines?

Of course not. What I mean is that just because N machines all
support windows, or similar user interfaces, that does not mean
that they are alike in other details of the operating system.

Portability depends a lot on what the program does. For example,
a V8 program that makes heavy use of streams probably take a bit
of work to run on a non V8 Unix. Or a BSD program that depends
on the 4.2 behaviour of signals might have problems. Or look at
all the problems with tty drivers and time functions between
various Unix implementation. These Unixes are a lot closer to
each other than the Macintosh and the Amiga and the ST are!

Good implementations of stdio can do a lot to help. An example
is the MegaMax implementation on the Mac. If you attempt to
printf or putchar on stdout, and you have not initialized

QuickDraw and the window manager yet, it will notice this, do it
for you, and create a window called "stdout", which looks a lot
like a TTY in cooked mode. For example, echoing, ^S, ^Q, and
backspace work, and there is a way to kill the program with a key
sequence. ^D generated EOF. So most programs that just want to
interact with a user, and do some computation will port just
fine. I believe that the other Mac C systems do similar things.
I don't know anout the ST and the Amiga, but if they don't
already, they can certainly be made to.

But when I write a program on the Mac, I want to use menues,
graphics, dialogs, etc. In short, I want to use the Mac
interface. If I had an ST or an Amiga, I would want to use their
interfaces.

It should be possible to develop a graphics library that is
implementable on the Mac, Amiga, and ST, so that one could write
portable programs that do graphics. It would probably not fully
utilize each machine, e.g., collision detection on the Amiga, but
most programs would be able to use the library.

I suppose one could also come up with menu libraries, window
libraries, text libraries, etc, so that one could write portable
programs that make use of the user interface available on the Mac
and Amiga and ST.

Until someone actually writes those libraries, I don't think one will
see a lot of portable code between these machines, except for programs
that use a simple command line user interface.

This specs for the above mentioned libraries could be a fun topic
to discuss (certainly more interesting than curly braces and bouncing
balls!).

Sounds like a job for an ANSI committee! :-)

Keywords: WHO CARES ABOUT A FUCKING NEW JERSEY AMIGA USERS GROUP
Xref: watmath net.micro.amiga:1029 net.micro.atari:1916

Why is most of net.micro.amiga cross posted to net.micro.atari? And why is
most of the ST stuff cross posted to net.micro.amiga? Maybe the groups
need to be re-organized:

```
     net.micro.atari                 8 bit atari stuff
     net.micro.amiga_and_st          Amiga and 520ST stuff
```

This would come closer to recognizing reality.

The "out of registers" error is a result of poor compiler design.
When generating subroutine calls the Hippo C compiler generates code that

moves each argument into a data register before moving it onto the stack. Unfortunately it does not reuse the data register, so that when you have a call with more arguments than available registers the compiler will halt with the error "out of registers". Of the 8 data registers in the 68K only six can be used this way (a Hippo issue, not hardware). So a call to the VDI routine "v_ellpie()" which has 7 arguments will not compile (even though it is "supported" by Hippo).

For example, if a program contained the following subroutine call:

```
v_ellpie( handle, x, y, xradius, yradius, begang, endang ) ;
```

where all the arguments are automatic variables contained in "main", the Hippo compiler generates the following assembly language:

```
move.w   -200(a6),d2
ext.l    d2
move.w   -198(a6),d3
ext.l    d3
move.w   -196(a6),d4
ext.l    d4
move.w   -194(a6),d5
ext.l    d5
move.w   -192(a6),d6
ext.l    d6
move.w   -190(a6),d7
```

whereupon it would halt with the "out of registers" error message. If there were enough registers, it would have continued with:

```
ext.l    d7
move.w   -188(a6),d8
ext.l    d8
move.l   d2,-(sp)
move.l   d3,-(sp)
move.l   d4,-(sp)
move.l   d5,-(sp)
move.l   d6,-(sp)
move.l   d7,-(sp)
move.l   d8,-(sp)
jsr  _v_ellpie
```

Because of this and their copy-protection I do not recommend this compiler to anyone.

How do I read the joystick ports on the 520ST via Basic? I didn't
see STICK() or STRIG() or MOUSE() :-) anywhere in my manual.
Where do I peek()?

Thanks!

Summary:

OSS used to distribute a bunch of routines on a separate disc
called a 'programmers library' or something along those lines
(NOT to be confused with the run-time library) that contained
various useful routines like character manipulation/transalation
stuff, routines for PM graphics, and also had the floating point
functions; most of the stuff would pop in as in-line ML code, though
all the use had to do was include the code and call it like a
regular function. The name of the disc was later changed to the
'Action toolkit', and it can be obtained from OSS or picked up
somewhere for $15 or so. Its definitely worth the money.

The CompuServe OS9 Sig. Copyright 1985. Reprinted by permission.

*** Attention Atari ST owners: You say you want a powerful, flexible, multitasking, multiuser operating system for your Atari ST? Well, you're going to get it! A company, whose name I can not yet mention, is now in the process of porting OS9 to the Atari ST! Believe me, I know. I will also be a beta tester for ST/OS9, so as time goes on, I will be able to answer most questions you may have.

Designed by Microware Inc., OS9 is a Unix-like operating system, with much of the power and flexibility of Unix, but without the price or size! It is, and has been for about 6 years, running on a variety of 6809 and 68000 CPU's, including Gimix, Smoke Signal, SWTPC, Tandy Color Computer, Hazelwood, Helix, and UniQuad. It has recently been announced and is being distributed with a 68000 coprocessor for the IBM PC/XT/AT! It is also in the process of being ported to the Commodore Amiga. It will be available possibly

during the first quarter of 1986, or the second quarter at the latest.

OS9 comes with a full complement of utilities, pipes, and filters, just as Unix does. It also provides access to a wide variety of business software, and a wide variety of programming tools and languages, including C, Pascal, Basic09, Fortran, and Cobol.

Stay tuned to the CompuServe OS9 Sig for news of this new product for the Atari ST, and for constant news, information, technical assistance, and public domain software.

Remember, you heard it here first! Please pass the word, and when you want to visit the OS9 Sig, just type "GO OS9" from anywhere on CompuServe! The OS9 Sig is dedicated to the promotion of OS9 and OS9 information, and to helping OS9 users. We have been open for 3 years and we are 1000 members strong at this moment. We are also the repository for the international OS9 Users Group Software library, and we are the largest single common gathering and information point for OS9 users, no matter what computer is being used.

Wm. A. Van Nest "Van" 76703,467 SysOp of the CompuServe OS9 Sig

I thought some of you might be interested to know that Philips and Signetics have anounced they will start producing a CPU called the 68070. It will be fully 68000/68010 code and bus compatible and have an on chip memory management unit, 2 high speed DMA channels, serial port, I2C bus interface and three counter timer functions in

one 84pin package (the extra pins are for the peripheral interfaces).
It will use low power CHMOS so as not to draw more power than your
68000 already does. It will have the instruction continue capacity
of the 68010 for virtual memory.
    This would make a nice (and easy) upgrade to any ST (or Amiga).
Just pull out your 68000 and put the 68070 on a little board that
maps all of the 68000 bus pins to the right places. I hope some
hardware hacker out there is listening.

Timmy,

Usually when one has a beef with a particular article posted to the net, one sends a meesage to the author and not to the net as a whole. Since you have sent your message to the net, this reply should also be as public.

Do you have a problem expressing yourself with the aid of profanity? Or perhaps your command of the language is so limited that the thought that you could express the same intent with fewer words just didn't come to you. Maybe it did but you are too bloody mindless to recognize a good thought unless it bites you on the ass.

The discussion of what material should be sent where has been beaten to death (or maybe you can't remember back that far...or maybe you can't read at all and when someone read my notes aloud to you you got the wrong impression?)

I sent my posting to net.micro.amiga rather than nj.general because I don't believe I'd reach enough New Jersey, Pennsylvania, and New Yorkers that way.

I sent my note to net.micro.atari because, as I mentioned, the INTERESTED PUBLIC is welcome. I thought that atari fans would appreciate a chance to gain more information about other computers.

Now, Timmy lad, what really do you a have problem with? Are you mad because by saying ``interested public'' you, being a proto-simian blob, were left out?

I'd like to hear your explanation - but do it in private. Sending any thing else to the net would certainly mean you;d only embarras yourself further.

Can anyone recommend a C or Pascal compiler for the ST?

Can anyone recommend a disk copying program (that handles protected disks)?

Can anyone recommend a RAM disk program?

In Atari Logo, is there any way to have the flow of control constructs control the execution of more than just one line? For example, the following works:

```
repeat 4 [forward 100 right 12 back 40]
```

but this doesn't

```
repeat 4 [
forward 100 right 12 back 40]
```

The Atari Logo manual mentions that there is a comment delimiter, and I believe it is ';' - but I couldn't get it to work. Does anyone know how to place comments in Logo programs?

Thanks in advance,

Eric Terrell CSNET ADDRESS terrell@OHIO-STATE

Richard,

Thanks for sharing your knowlege of the Atari ST joystick/mouse ports with us. Not konwing how to access the joysticks has been driving me

crazy for a couple of months now. I am anxiously awaiting the next exciting installment (especially the example C source code).

John

Chuck, Regarding your desire for someway to standardize the way extra memory is addressed in the 8 bit ATARIs, I have come to the conclusion

that we have to accept ATARI's way of doing things, e.g. via the bank select address at $D301. And I see why ATARI did it this way instead of using the well established adress of $CFFF used by AXLON: they already had $D301 decoded so that no extra logic was involved. Other than this difference, the extra memory of AXLON and ATARI look the same (i.e. the memory banks are mapped in the same place from $4000-$7FFF). I have even considered adding to the AXLON ramdisk handlers built into the OMNIMON and OMNIVIEW for the 800 the ability to convert refences to $D301 into references to $CFFF so that programs written to run on the 130XE and 800XL's with compatible upgrades would also run on the old 800 with an AXLON ramdisk (or its compatible). I may eventually do this, but for now it is too far down on the priority list to think about.

As far as an extra memory 'handler' which would allow programs to address the extra memory banks as if they were merely an extension of the 6502 address space, the only practical solution that I can come up with is to buy an ST.

>
> This would come closer to recognizing reality.

For god's sakes, don't make me wade through a bunch of atari stuff
hunting for the amiga news I'm interested in. The stupid debate is
finally settling down, and we're getting some actual information
across on net.micro.amiga. The Amiga and 520ST are two different
machines. Why try to talk about them both at the same time? It
just makes actual quality programming that much more difficult.

Atari owners: read/post to net.micro.atari
Amiga owners: read/post to net.micro.amiga

Isn't that nice and tidy? And efficient? I LOVE efficiency. :-)

Lee

I'm looking for information on the AtariWriter Plus program.
I already have AtariWriter in ROM on my 800. What does Plus buy me?
A salesman could only tell me that it has a dictionary.
Will it run with only one disk?
Will it run on the 800 with 48K of ram?
Will my old AtariWriter files be readable by Plus?
Do I still need my old AtariWriter ROM to run Plus?

Thanks for any info.

~~~~~~~~~~~~~~~whoa lineater~~~~~~
i have seen PC InterComm and i can't praise it enough, it is a full (as
best i can tell) vt100 emulator with such features as kermit and
xmodem protocals, and screen grap; its also very easy to use with
user definable setup files. Only problem is i cant remember who
makes it but your local atari store should be able to help you.

You are correct. A beef with a particular article should be handled
by mail. What I should have done was mail your a short complaint about
your article, and posted an article under a new title about the cross
postings. Sorry about directing a general flame at a particular article.

>

>and New Yorkers that way.

It sounds like it istime for someone to make a 'ne' distribution
for New Jersey, New York, Pennsylvania, etc. Could someone over
in that area create such a distribution? Or merge all those
little states into one proper state :-)

>
>I sent my note to net.micro.atari because, as I mentioned, the INTER-
>ESTED PUBLIC is welcome. I thought that atari fans would appreciate a

Can Mac owners come too? Why not post to net.micro.mac then? How about
IBM PC owners? Why not cross post to net.micro.pc? Most users groups I
have heard of allow anyone to come. Is the NJAUG different? What would
happen to the net if everyone with a users group posted announcements of
meetings to every other net.micro.* group?

>Now, Timmy lad, what really do you a have problem with? Are you mad
>because by saying ``interested public'' you, being a proto-simian
>blob, were left out?
>
Are you saying that proto-simian blobs are not part of the general public?
I am going to have to call the ACLU or the ALF to deal with you! :-)

ps: ignore the mail I just sent you about this. I have been having
mailer problems, so it probably won't get to you. Even if it does,
it really doesn't say anything not said in this article.

>   -Richard Hartman

To me there are only a few important differences between the two machines:

   1a. The Amiga is NTSC compatible which allows easy use with VTR's, home
       tv cameras for digitizing/overlaying etc. at the expense of flicker
       at 640x400.

   1b. The Atari is virtually flicker-free at 640x400 at the expense of NTSC
       compatibility.

   2a. The Amiga supports up to 4 bit planes in the max resolution mode,
       enough for decent grayscale digitizing/imaging, palette of 4096, and
       bit-blit & sprite hardware.

   2b. The Atari supports up to 2 bit planes in the max resolution mode, with
       palette of 512 and little or no hardware graphics assistance.

   3a. The Amiga supports a series of dedicated DMA channels that DO NOT
       INTERFERE with the CPU speed for 4 sound channels that utilize a
       wavetable (up to max available of the internal 512k ram) and associated
       volume and pitch tables, which effectively constitute a 4 channel
       8-bit digital sampling synthesizer a-la Ensonique Mirage but with
       4 channels instead of however many the Mirage has.

   3b. The Atari uses a off-the-shelf 3 channel sound generator that's been
       around for awhile, and from all reports is not terribly sophisticated.

If, after all that, you still can't tell the difference between the machines
except price, then by all means buy yourself the 520ST. Someone should, as I
am a firm believer in healthy competition. But for me, I bought an Amiga,
the least expensive system that could do what *I* needed in a machine,
because the 520ST couldn't do those things at all (imaging at 640x400,
NTSC video compatibility, and digital sampling of sound).

I haven't seen Hippo-C on the ST, but if it is like the Mac version, then
I believe only the linker checks the copy protection. So you will have to
use the original disk every time you link. But you should be able to use
the compiler from a copy of the original disk. This is still "yuk!", but
at least it's not as bad a "yuk!".

Also, call Hippo and see if they will sell you an unprotected disk. They
were doing that for the Mac (it was $25 for the unprotected disk).

Can the ST handle single sided disks? If it can, it would be interesting
to see if a bit copier on the Mac, like Copy II Mac, could duplicate
Atari disks on a Mac. Copy II can handle Hippo-C on the Mac, so maybe
it would work for the ST? (or do they have Copy II ST yet?)

How does one generate a BREAK on the ST in VT52 emulation mode? Failing that,
is it possible to generate it through an xbios call? Thanks for any help.

I just bought my Atari 520ST over the weekend and have been
reading the sparse documentation. I have a couple of questions:

1) The DR LOGO documentation makes no mention of functions
   that access the sound capabilities of the ST. This seems
   like a glaring omission. Has anyone written any routines
   to provide access to sound?

2) I understand that the $300 developers package has lots of
   system details. Is there any other publication that provides
   information at a cheaper price? I've seen ads for a series
   of 4 books on the insides of the ST. Has anyone bought these
   books? and if so are they sufficient?

3) Are there any ST user groups in the Boston area?

Thanks.

Summary:

In article <8512061148.AA25696@ucbvax.berkeley.edu> terrell@OHIO-STATE.CSNET (Eric Terrell) writes:
>Does anyone know what to do about the "out of registers" error message
>in the HIPPO-C compiler?
>
Yes. It will occur whenever a subroutine call requires too many registers to hold all the intermediate results before putting them on the stack. Someone's register reclemation algorithm could use a little fine tuning. In particular, constructs like

```
a = foo(bar[i].left, bar[i].right, ... );
```

will get the error. However, it can be recoded as

```
t1 = bar[i].left;
t2 = bar[i].right;
...
a = foo(t1, t2, ... );
```

What a hack eh?
>Also, is it possible to start up with the original disk and then change
>to a copy of the disk? With my single-drive system I am currently
>unable to use the compiler unless I use the original disk (yuk!)
Oh yes.. There is documentation on how to do this supplied with the compiler, but..

(a) initialize a new disk
(b) copy everything but hos.tos to this new disk. DO NOT USE A SECTOR COPY.
(c) To run, boot on HOS.TOS on the supplied disk, eject it and insert your copy. You should do a 'ls' to get the new disk directory information set up properly.

NOTE: If you have a one drive system, go an borrow a 2 drive one for step (b). There are 40 or so files that have to be copied, 3 disk swaps per file = 120 disk swaps.

They suggest that you do not use a sector copy. I would assume that

their protection mechanism either (i) will cause the sector copy to
abort, or (ii) foul up the protection on their disk.

Unfortunately, the ANSI bureaucracy has done just that, and called the result
GKS. If anything it serves only to show the futility of the effort. In order
to be all things to all people in all ways, any such implementation must be
huge, slow, unwieldy, and generally unusable. Guess what? GKS is huge, slow,
unwieldy, and generally unusable. It is appropriate only for those with
giant machines, the likes of which the world doesn't use much any more.

-Brian Diehm
Tektronix, Inc. (In this case, my opinions directly oppose the official Tek
                 policy - Tektronix is publicly committed to GKS, and must
                 be to support a portion of its customer base. But really,
                 if you probe deep enough, some of the people in charge don't
                 really like it . . .)

<Here, line eater .. here, boy .... >

I am looking at an inexpensive CP/M system for home. I also have an
800XL. I understand that a CP/M box with a 19.2Kb serial port can be
made to look like an Atari disk drive. I have seen some material
from CPMUG to support such an application. Anyone else done this?
Benefits/drawbacks? I would suspect that copy-protected material
would probably choke in this arrangement, but that is not a concern.
Please reply by mail. Thanks in advance.

Look in the back of Computer Shopper for really good deals on cables
and power strips. I bought a sheilded ibm printer cable and a surge
protected power strip for $10 and $13 each. Needless to say one
should exercise some caution in going mail order, although for small
items such as these the risk is low. The prices you quote are
usually locally available at discount computer stores. At least
they are in the local Washington D.C. area.

Sorry, the above are very useful, but not *vital* to running unix,
especially on a personal computer. I would bet my terminal that
there will be a unix port in six months to a year. It might not be
full system V, but the idea and upward compatibility should be there.

The biggest obstacle to Unix on the ST is the gap between the people
with source licenses and the people who want to do things with ST's.

The simple hardware/sortware architecture of the ST should actually
make it a much easier port than to the Amiga or Mac, since you are
giving away less of the special features when you switch to the Unix
model.

   So, Keith Doyle bought an Amiga. Thanks for letting us in on this fact, Keith. (* end sarcasm *)

   Can we have some *Atari* postings here? Although I'm an 8-bit Atari owner, I don't mind reading through the ST information; I *do* mind seeing mindless bickering over which machine better suits someone's personal desires. This is an Atari forum, and should be kept that way. Likewise, the Amiga group shouldn't be inundated with this crap either. How about a cease-fire agreement? That way, the ST owners could spend their time and net-space reviewing the $1000 worth of software that they bought with the money they have left because they didn't buy an Amiga :-).

I would like to upgrade by brothers 520ST as his Christmas present.

Any information about doing the upgrade would be appreciated.

Thanks in advance

How does the Amiga sample sound?? I have heard this many, many times, yet no-
one has ever mentioned an ADC in the machine, only an 8-bit DAC. (By the way,
does this DAC have the proper anti-aliasing filters?)

Can anyone give me a "consumers' reports" recommendation on word processing
packages for the ATARI 800XL? I would like to write lengthy documents (e.g.
books) and wonder how practical it would be to do this on the ATARI.

In this regard, does anyone have any experience with modifying an ATARI 800XL
to run an 80-column display for text only or text and graphics? Is this
practical?

By the way, I have access to information on the parallel bus connections on
the 800XL, as well as some hardware and software related to ham radio
applications - slow-scan TV reception (e.g. pictures from the space
shuttle on some recent missions), Morse code keyboard operation (uses one
external relay connected to the cassette start/stop line if you want to key a
transmitter) etc.

Thanks for any answers that are available. Please send them to me at
jhs @ mitre-bedford, as I just sent in my request to get on the mailing list

and am not yet receiving postings.

Perhaps this explains why I found the atari machine I looked at yesterday
to have, in general, a much crisper and pleasing color desktop. Perhaps
some readjustment of the default Amiga workbench colors would help.
As a new Amiga owner, I am still satisfied with my choice, since for *me*
it is the correct one for the things I want to do with the machine.

By the way, you didn't mention the command line interface on the amiga.
I would sorely miss this on the atari.

In all, I thing both are nice little machines, and I hope they both
do well in the marketplace.

-Fred

After reading a lot of articles about this years Comdex it is becoming more obvious that Atari has already won in the ST vs. Amiga wars. The main complaint about the ST was that there was no available software. There was plenty of software to be shown at the show. Commadore did not show up. After reading articles in many magazines about Commadore's financial woes, the speculation that they were too broke isn't hard to believe. Also, a lot of the touted software for the Amiga has yet to hit the shelves. Atari has sold more than 100,000 520STs and now that the software is available, distributors are again having a hard time keeping up with demand for 520STs. A few calls to Atari retailers, especially the mail order people can verify this. I predict that unless Commadore can do something really spectacular to turn this around that the Amiga will fade away by the middle of next year.

A side note for ST fans:

Atari is now marketing a 1 meg ST in Germany with a built in disk drive. Supposedly the ST is the #1 best seller in that country.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

the latest word i heard from inside Atari is that they have dropped
plans to do unix for the ST because it does not provided sufficient
memory protection for unix to work properly.

>Metamaco (sp?) was/is (?) working on a Lisp for the ST.
>Don't know if this is still in progress or what.

According to the January 1986 issue of ANTIC (TOC coming soon), they are going to carry all the METACOMCO software for the ST. The MACRO ASSEMBLER and META PASCAL should be available pretty soon. The LATTICE C is still in alpha test and will follow later. The CAMBRIDGE LISP and the IBM PC CROSS DEVELOPMENT SYSTEM have been announced but are not finished yet if I understand the article correctly.

The MACRO ASSEMBLER and the META PASCAL will cost $79.95 and $99.95 respectfully. All METACOMCO languages for the ST include the METACOMCO Screen Editor and detailed manuals.

If you have technical questions and want to talk to a System Software Engineer, call toll free 1-800-GET-META.

Hope this helps...

>How do I read the joystick ports on the 520ST?

Good Question! I have asked it twice on the net already. If anyone
knows please post the answer so that we will all know.

Thanks,

John

I've had an Atari Asm/Ed cart. for a while but am now getting more into
writing and debugging assembly language code. Before I got the cart. I
remember reading about "tricks" that can be done to make the cart. more
useful such as disassembling memory to disk or undocumented features.

If anyone knows what I am talking about please give me a pointer to the
source of such information, or if you know some ways of making the
Asm/Ed cart. more useful let me know.

                  Thanks,
                  Owen Alexander   ..!houxl!oaa

PS: Any useful info received will be compiled, summarized, and posted to
    the net.

   One (of the many) things ATARI didn't mention in their bouncing ball
display was that this is an EASY, EASY, EASY demo to do! I'm pretty sure
(and don't you DARE call this bluff!!) that I could produce an acceptable
version of it to run on the Apple II! Instead, ask Atari if 1) there's
enough processor bandwidth left while it's running to do a LOT of processing,
2) if there was sound to go with it, synchronized with the ball, and 3) How

long it took them to GET that display - I'd be willing to bet that they had several of their hottest-shot programmers working on those, and do you really think that they would bother to make the Mac version as pretty?
   The impression I get of Atari lately (and don't get me wrong, I basically like Atari's stuff) is that they will stop at NOTHING to get the public to believe in their superiority, and if this includes providing insufficient information for a true, objective comparison, well, thats the way it goes. Personally, I find this kind of marketing scheme insulting not only to the technically competent people like us, but even more to those who can't know any better.

The short answer to the question of why the ATARI seems to behave properly even when garbage is written into the JVB instruction at the bottom of the Display List is that the 6502 initializes ANTIC's program counter during every Vertical Blank Interval, thus overwriting the garbage with "good stuff".

For those of you that are interested and to whom the above paragraph raises more questions than answers, I have included the long answer below.

Enjoy

Ron Perloff
Burroughs DSG

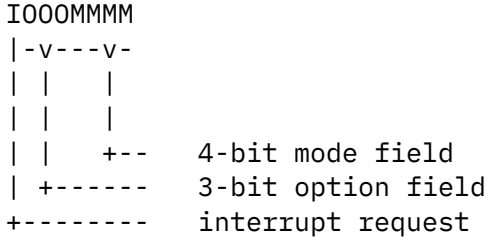
Home: 17040 Oculto Court
San Diego, CA 92127

The ANTIC chip is a special purpose microcomputer that happens to execute graphics-oriented instructions instead of computational instructions. The instructions consist of a one-byte op-code which in some cases is accompanied by a two-byte operand. The op-codes take the form:



When the interrupt request flag is on, ANTIC generates a Display List Interrupt, DLI, to the 6502 at the beginning of the last horizontal scan line caused by the instruction. The interpretation of the option field depends upon the value of the mode field.

ANTIC interprets the 4-bit mode field as follows:

MODE 0 --> DISPLAY n+1 BLANK LINES

The three bit option field specifies the number, n, of lines to be displayed in the background color; e.g.:

```
00000000 ==> DISPLAY 1 BLANK LINE
00010000 ==> DISPLAY 2 BLANK LINES
10100000 ==> DISPLAY 3 BLANK LINES,
              DLI AT START OF 3rd LINE
```

MODE 1 --> JUMP INSTRUCTIONS

The jump instruction always includes a two-byte operand field, in low/high format, which indicates the location from which ANTIC will take its next instruction. ANTIC performs the jump like any microprocessor, reloading its program counter with the value in the operand field.

When the left-most bit of the option field holds a "0", ANTIC displays one blank line and performs the jump. When the left-most bit of the option field holds a "1", ANTIC suspends operation until the end of the vertical blank interval. In both cases, ANTIC ignores the remaining two bits in the option field.

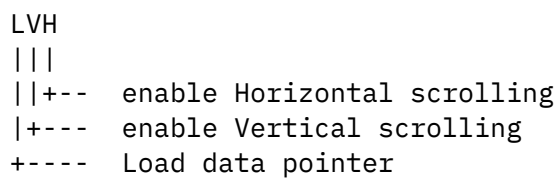
ATARI calls the first form of the instruction "JMP" and the second form JUMP VERTICAL BLANK or "JVB".

MODES 2-F --> DISPLAY INSTRUCTIONS

ANTIC interprets all of the remaining instructions as display instructions. In the character modes, 2 through 7, each byte of screen data indicates an offset into a character set. The character modes differ from one another in the interpretation of the bits in the character set and the height and width of the characters.

In the map modes, 8 through F, the bits of screen data identify which the register whose 8-bit color description is to be displayed. The various map modes differ in the number of bits included in each pixel and the height and width of each pixel. Pixels may contain either 1 or 2 or 4 bits.

The option field contains three independent flags:



When the LOAD flag is on, ANTIC loads its data pointer from the operand field of the instruction before beginning to fetch screen data. When the LOAD flag is off, ANTIC merely continues taking screen data from the place that the previous instruction left off.

The Horizontal and Vertical scrolling flags allow ANTIC to perform fine scrolling on the display. ANTIC takes the scrolling offsets from on chip registers. from where the previous

instruction left off.

The 6502 gives ANTIC's program counter its initial value, the top of the Display List, by storing low-byte/high-byte into DLISTL/DLISTH, D402H/D403H. Once ANTIC begins executing the display list, ANTIC can theoretically keep going because the JVB instruction at the bottom of the display list brings it back to the top.

The designers of the ROM-resident operating system for the ATARI very wisely decided to load a new value for the starting Display List location as part of the vertical blank interrupt procedure. They take the address from a "shadow" location in RAM, SDLSTL/SDLSTH or 230H/231H. Of course this overwrites the address that the JVB instruction at the bottom of the display list places in the ANTIC chip's program counter.

In article <395@ssc-vax.UUCP> warren@ssc-vax.UUCP (Warren Kring) asks questions...
Commodore-Amiga has *NOT* filed chapter 11 - not even considering it.
We are manufacturing *LOTS* of computers, (not just Amigas).

Sorry, I do not have a firm date on updated DOS user's guides... BUT the current stuff should be available to any dealer who orders it.

The clock (and date routines) got significantly better in V1.1. You can still be off about 4 seconds (or was that minutes, I forgot) a day.

The "real" V1.0 version of Textcraft will only allow you to access the files in 1 drawer at a time. Please address any "flames", product enhancment requests, etc to Arctronics. The drawer you get to List, Load, and save using is the one containing the document you started with. You can use >1 drawer, you just have to leave and reenter Textcraft to do it.

V1.1 Notepad prints just the text, no borders, in graphics (fancy fonts) mode.

(-- Sorry for the long messages in the past, I'm trying to keep them shorter now. BruceB. --)

Awhile back there was some discussion about porting OS-9 to run on the ST. Has anyone done this? Is anyone planning to? Is it still a reasonable idea?

Any comments are welcome,

I have a brand new 520ST. Is there a way to create 10000 by 2 arrays in BASIC? The best I can do is about 2200 by 1 with BUFF GRAPHICS off and with a program that takes up only 200 bytes. Thanks.

ST World
========
by Joe Waters

COMDEX '85

A lot of potential ST owners have chosen to sit on the sidelines waiting for the appearance of appropriate software before actually jumping on the ST bandwagon. Well, friends, it looks like you can now jump safely. Atari devoted its floor space at the massive, seventh annual COMDEX (COMputer Dealer EXpo) almost entirely to dispelling the notion that there is no software available for the new

520ST computer. I counted about three dozen different companies proudly displaying their newly released (or soon to be released) ST products. When Santa Clause brings that new ST for Christmas, your biggest problem is not going to be finding programs, it's going to be deciding which software to buy!

I am writing this column while COMDEX is still in progress (CURRENT NOTES is already late in getting to the printer) so the whole story of this year's show isn't complete yet. In addition, I simply don't have the space to cover in any detail all the companies and programs that were on display. So let me just pass on some general observations and a quick overview of some of the products I was particularly impressed with.

The thrust of ST development work is centering on the ST as a personal productivity machine. Although there were some delightful new entertainment programs being shown, these were in the minority. Programmers will find an abundance of computer languages and programming aids. Business users will find many variants of their standard tools (word processors, spreadsheets, and databases). Other professional users, such as accounts, engineers, architects, etc, will be delighted to see software coming out with their specific needs in mind. The ST is simply too powerful to be used only for entertainment.

Not all ST products are being released by bright young programmers seeking to make their fortune. A very large number of programs are being introduced by mature software companies that are porting their programs over to the ST or developing whole new programs to take advantage of the ST's unique features. You still won't see some of the higher-priced companies from the IBM world (Lotus, Ashton-Tate, Microsoft, etc.) rushing to put their programs on the ST -- the lower prices required to sell in the ST market would have a detrimental impact on the pricing structure employed in the profitable MS-DOS market. But you can expect the firms that have pioneered low prices in the IBM world, such as Borland International and DAC Software, to release ST versions of their products and do quite well.

So much for generalities. Just what was there? Here are some highlights.

SPREADSHEETS. The long awaited VIP Professional had finally shipped the week before COMDEX and was proudly on display with finished packages ready to go. Dan Nelson, the product manager for VIP, tried to show me the great manual provided with this LOTUS look-a-like, but I wasn't particularly interested. The manual may, indeed, be better than the one provided by Lotus but the fact that VIP was code-compatible with 1-2-3 meant that I, like many other users, simply won't need a manual. Just boot up the program, and once in the familiar 1-2-3 setting, simply start working. IBM users may find an additional bonus. It was the speed of execution which helped propel 1-2-3 ahead of the competition in the IBM world. Dan

claimed that VIP on the ST was not only compatible with Lotus, but faster!

VIP wasn't the only spreadsheet available. Kuma Computers Limited was demonstrating A-CALC which will be marketed by Antic. The Kuma rep claimed that only a final round of quality assurance testing, was needed before the program was officially released.

Integrated Packages. Two other spreadsheet programs were announced as part of integrated packages. Rising Star announced seven modules for the ST: RSI Spreadsheet, RSI Graphs (business graphics), RSI Draw (computer-aided design), RSI Paint, RSI Scheduler, and RSI Music (single track MIDI sequence recorder). The music program provided attendees with audio entertainment as they surveyed RSI's products. RSI has been a major developer of software for the Epson line of computers.

The other integrated package, called SoftPac, was introduced by Softronics Computer Systems, a major producer and marketer of vertical market software for the IBM PC and other computers. Besides the spreadsheet program (SoftCalc), SoftPac includes a word processor (SoftWrite), database management (SoftBase), communications (SoftComm), and computer aided design (SoftDraw). Steve Hansen, the president of Softronics, told me that, the day before the show opened, a distributor purchased 60,000 copies of the package. At least somebody expects a lot of STs to showup in the marketplace!

DATABASE PROGRAMS. AtariSoft and Stoneware jointly introduced a new (as yet unnamed) filing system for the ST. Some readers may recognize Stoneware as the company that produces DB Master, a high-performance database management system in the MS-DOS market. Stanley Crane, the author of DB Master, gave me a quick demo of the Atari filer. He had a sample mailing list database of 1,000 names indexed on the last name. Gee, that was getting close to the size of the database CURRENT NOTES has to contend with. I asked him to sort the database on the zip code field -- a task that would take SynFile on the 800 about an hour (I'm guessing here since I long ago gave up trying to maintain our mailing list in SynFile). On a COMPAQ with a hard disk using dBASE III, the sort takes a little over two and a half minutes. On the ST? I had to ask Stan to sort it twice since I wasn't paying enough attention the first time -- it only took 2.5 seconds! Obviously, everything was done in RAM and so there is a limit to the size of database the program can handle, but I was impressed nonetheless.

Interested in a more powerful, but still user-friendly database package? Paul Heckel, author of The Elements of Friendly Software Design, and president of QuickView Systems was demonstrating a new "software metaphor" called ZOOMRACKS. This product is really a database management system in disguise. Picture a rack of cards, such as at a time-clock when workers have to punch in and out. You can only see the first line of each card, but if you pull the card out, you will see much more information. That is the concept upon

which Zoomracks is built. Move your cursor down to a name and click. Now you see the entire card. To give Paul a little test, I asked him to reindex a sample mailing list database, where cards were listed by last name, to a list based on the state code. The state code was on the fourth line of the card mixed in an alphanumeric filed with a city, i.e. "Las Vegas, NV". Guess what. Paul was able to build a macro on the fly that split off the state abbreviation from the city, moved it to a separate, newly created field, repeated this process on the entire database, and then sorted on that field. Wow! This simple rack concept has much more power in the product than a first glance would reveal.

You say you have already spent two years becoming familiar with dBASE II and aren't interested in learning another database program. Lucky you. You have several options on the ST. Holmes & Duckworth were showing the current version of H & D Base (to be released in mid-December). H & D Base is command file compatible with dBASE II. If you know dBASE, just boot up this program and start working; all your dBASE commands will work just as they did on your CP/M or MS-DOS system. (If your are a developer, you have an added bonus. Since H & D Base is merely an extension of the H & D Forth language system under which it was developed, the full range of unique Atari 520ST capabilities, including windows, menus, dialog boxes, etc. is available. Your dBASE programs can tap into the GEM environment!

Owners of the ATR-8000 will love another option. You may already have dBASE II running under CP/M on your ATR8000. No problem. Just boot up the CP/M Emulator Program on your ST and now you can run your entire CP/M library! (Of course you'll have to transfer the programs to the ST's 3.5 inch disk format.) Not only can you use the commands you are familiar with, you can use the same program. The CP/M Emulator was not officially demonstrated at COMDEX, but Frank Nagle, head of the Bay Area Atari Users Group, managed to get a sneak preview from one of the Atari reps. Frank said the program had no trouble booting up WordStar and running it, in fact, running it faster than on his own native CP/M system!

Besides the above programs, and the ones announced in the integrated packages, Hippo had already shipped Hippo Simple, a "powerful, flexible and easy-to-use database," BMB CompuScience was demonstrating The Manager, "a full-featured database manager with on-screen forms and report writer", Regent Software announced Regent Base, "a full function relational database program" available by February, and OXXI Inc announced dbONE, another database program claimed to be 100 percent compatible with dBASE II files.

WORD PROCESSORS. Several word processors were already out for the ST before COMDEX. STWriter (no where visible at COMDEX) had been released "free" by Atari and HabaWriter, by Haba, and Final Word, by Mark of the Unicorn, were already on store shelves. I was able to see HabaWriter for the first time at COMDEX and also saw a demonstration of the new Regent Word as well as Regent Spell programs. For those of you who like the what-you-see-is-what-you-get

word processors, this one's for you. In previewing text, not only are boldface and underline shown in the preview, but elongated text is actually shown on the screen in double width and both super- and subscript are displayed just as they would appear on your paper. Regent Word, written by the developers of Atariwriter and Atariwriter Plus, also supports elongated, underlined etc. in their print preview. Poor spellers in the audience will certainly appreciate Regent Spell. Not only does it find the errant spelling (and show it to you in context), but it will give you 10 suggested correct spellings. It comes with a dictionary of 30,000 words which you can expand to 60,000 words. Both Regent Word and Spell are available now. And, finally, if you can't type as well as you'd like, you can always pick up Typing Tutor (including Word Invaders) by Academy Software to get your typing speed up to snuff.

Other word processors announced (although not necessarily demonstrated) were PaperClip and HomePak by Batteries Included, Hippo Word, Hippo Concept, and Hippo Spell by Hippopotamus, Word Whiz by Oxxi Inc., SoftWrite by Softronics, First Word by GST, and Word Processor by Spinnaker. For those interested in typesetting, Typesetter ST was demonstrated by Xlent and Andra/ST, a document processor for laser printers and FX80 compatibles, was announced by TDI Software.

LANGUAGES. If you have an inclination to do some programming, there will be more than enough langugages to choose from. Right now, you can use Atari's development package (C and assembler), ST BASIC (only recently released), or ST LOGO. Haba has released Hippo C and the Dragon Group has 4xForth. At COMDEX, TDI was selling their Modula-2/ST package, H & D were showing their Forth package, ANTIC had the META Macro Assembler and was also demonstrating A-SEKA, a 68000 ram-resident assembler from KUMA, and Philon was showing their basic interpreter, Henry, with a compiled version on the way. Further C compilers are coming from GST and Lattice. Prolog will be available from OSS and Fortran from Philon while Pascal programmers will be able to choose among products from META, OSS, Philon, Prospero, and TDI.

PROGRAMMING AIDS, such as ram disks and disk utilities were in abundance from a variety of producers. MichTron in particular now has a full scope of programming utilities including M-Disk (a ram disk), Soft Spool (a printer spooler), Michtron Utilities (examine & repair disk files), MI-Dupe (backup disks), and M-Copy (speed up disk duplication). If you really like to examine, in detail, your disk files, you're certainly in luck; you can now choose from the Disk Doctor from Antic, Toolbox (Vol. One) from H & D, Disk Utilities from Hippo, and Personal Diskit from OSS.

OTHER SOFTWARE. I wish I could go on about the rich variety of new entertainment and speciality software introduced at COMDEX, but I fear that if I tried, this issue of CURRENT NOTES would never get finished. In the months ahead, we will have ample opportunity to acquaint you with the best of each category.

HARDWARE. This was primarily a software show. Atari announced no new hardware products. However, there were several companies using Atari hard disk drives in their demonstrations. I was told that these 20-megabyte hard disks were being shipped to developers who had them on order. Indeed, the backlog of orders was just about filled. Retail channels will see these 20-meg drives by the end of the year. There will be no 10-meg drives, but a 30-meg drive may also be available.

Atari has decided not to produce a color printer for the ST. Why? Because Okidata had a color printer on display made specifically for the ST. And the quality of the color pictures? Certainly among the best I've seen produced anywhere! I was sorry I had to leave before getting to the Okidata booth to ask some more about this marvelous printer.

How about TOS in ROM? Neil Harris, publisher of Atari Explorer, told me the operating system was set and that the program was going out on Monday (November 25) for mass production. Developers would get the ROMs very soon and retail channels would begin seeing the ROMs appear before the end of the year. Early user group purchasers were promised free upgrades to the operating system. Dave Duberman, Atari User Group Coordinator, confirmed this and said he would be sending the ROMs out when they became available.

There was a hot rumor just before the show that Atari would introduce a laser-type printer (i.e. laser-quality output but using a different technology), at a price less than $1,000. It was a nice rumor, but there was no such printer there nor would anyone confirm (or deny) the rumor. And, as you'll notice in the Antic report, there were no CD-ROM players available from Atari -- so far Atari has not found a supplier willing to sell the drive at the price Atari wants.

AI on the ST. Before I close, I must mention a delightful little program from Hippo that I received shortly before going to COMDEX. It's called COMPUTER ALMANAC and if you want to impress your friends with just how clever your ST is, you'll have to get this program. While they watch in amazement, you sit at the keyboard and ask your ST questions. Here is what a typical session might look like (my questions are shown in italics to help distinguish them from the Almanac's answers):

What time is it in Moscow?
It is Sunday, 5:01 AM in Moscow, Soviet Union when it is Saturday, 9:01 PM in Washington, District of Columbia.

Who won the 1980 Superbowl?
I didn't understand that.

Who won the 1980 Super Bowl?
The Oakland Raiders won against the Philadelphia Eagles in the 1980

Super Bowl (Jan. 1981), with a score of 27 to 10.

How many calories in an Apple?
There are 325 calories in 1 cup of apple or brown betty.There are 33 calories in 1 tbsp of apple butter.There are 410 calories in 1 piece of apple pie.There are 96 calories in 1 med raw apple.There are 234 calories in 1 cup of dried apple.There are 117 calories in 1 cup unsweetened apple juice.

What picture won the Academy Award for Best Picture in 1971?
The French Connection won the Academy Award for Best Picture in 1971.

How far is it to Las Vegas?
Las Vegas, Nevada is 2084 miles from Washington, District of Columbia.

How do you say "Hello" in Swahili?
"Hello" in English is "hujambo" in Swahili.

What is the area code for Reno?
The area code for Reno, Nevada is 702.

Who won the Nobel prize for Chemistry in 1982?
The 1982 Nobel Prize for Chemistry was won by Aaron Klug of U.K.

Well, I think you get the idea. Use free form English questions and the Almanac uses its own intelligence to interpret your question and give you an answer. The Almanac has over 35,000 useful facts. You could go on for quite some time asking a wide variety of questions and getting appropriate answers. But beware! Don't give the keyboard to your friends. It isn't that hard to stump the Almanac. It can only answer questions about things it knows and the first question coming from the peanut gallery is likely to be about something it doesn't know! But it certainly does know a lot and you can have loads of fun amazing your friends with Computer Almanac.

If you sent in your warranty/registration, then you will automatically
receive a copy of ST BASIC (with documentation) in a couple of weeks.
Both Atari-specific magazines, Antic and Analog, are good sources for
information on the ST.

Eric,
     If you send in your registration card you should get BASIC in the mail.
If you can't wait you should be able to find plenty of copies floating
around at your nearest Atari computer store or user's group. It is free
and not copy protected.

     John

Does anyone know what to do about the "out of registers" error message
in the HIPPO-C compiler?

Also, is it possible to start up with the original disk and then change
to a copy of the disk? With my single-drive system I am currently
unable to use the compiler unless I use the original disk (yuk!)

Thanks,

Eric Terrell

Some people seem to think that Atari was wrong to write its own version of Boing and compare it to the Amiga version. Two months ago it seemed like the Amigas stongest selling point was that it could produce graphics like those in Boing. Every one was saying how fantastic it was. Now that Atari has a version all you hear from the Amiga people is how simplistic the program is and just wait until you see what the Amiga can really do.

As far as I am concerned all that Atari was doing was saying "Hey, whats the big deal about a bouncing ball demo. We can do one that looks just as good." It seems to me that they were doing a service to the general public by showing people that one bouncing ball program does not a computer make.

I am not saying that this means that the Atari ST has the graphics capabilities that the Amiga has. It doesn't. On the other hand, I have yet to be convinced that the Amiga has enough special graphics to make up for the additional price ($1000 vs. $2000). Though it may seem that I am biased in Atari's favor, actually I like both machines very much. I just wish that people wouldn't get so indignant about a little healthy competitive marketing hype. So, Atari put the monocrome price on the color monitor in their magazine ads, and Commidore shows light streaming out of their monitor during the birth of a star child in their TV ads. The two companies alone will produce more than enough hype. I don't think that we need alot of "my computer is better than your computer" fanatics fanning the flames.

John

One of the interesting sidelights to this conversation about
bouncing balls is that the Atari version takes up about 11k
on disk...and i was told that the Amiga version takes up about
300+ k. Is all that extra disk spaced used to store the data
for the sound?

I have also seen the 8 bit Atari machine 130XE (?) with the
same bouncing ball demo...personally i didn't detect a radical
difference in all three (st,amiga,130XE) demos...and if i was
looking for a cheap machine to run bouncing ball demos on
i would choose the 8 bit 130XE.

To Eric and anyone interested:
Atari has said that anyone who has sent in their
warranty cards will receive Atari BASIC and the BASIC manual.

If you can't wait to get the BASIC from Atari, let me know as
I can send you a copy of BASIC (I only have the program itself --
no documentation). If interested, send a check for $3.00 made out to:

*** replace this line with your AMIGA or IBM/pc ***

After careful consideration I have decided to get
an ST instead of an IBM/pc, any of its clones, or
the Amiga (which I consider good for games, but
bad for any other hacker-type of work).

Anyway, I don't want to compare machines, but get
and ST. Furthermore, I'd like it to have 2 DOUBLE
density disks, a decent printer, and ONE MEG (at
least) of memory. I've been trying to find a dealer
carrying the ST in the West LA area without success,
and I wonder why they are hidding them (it's almost
Christmas!). Am I asking for too much?! I don't want
to "place an order", as I'm leaving the country quite
soon.

I'd appreciate any suggestions. I'll post the useful
answers I receive.

Sorry I forgot to include this, but the best magazine I've seen for the ST would have to be Antic. Of course there is also Analog, but I haven't been as impressed.

Anybody seen the game "Hacker" for the ST? It is supposed to be *awesome* I will be able to give a review in the near future...

Wishing for an ST, right Santa?

Aloha,

*** replace this line with your four letter word ***

I'm trying to buy an ST, but I don't know which monitor

or printer to use with it.

I wonder if the color monitor is good enough to steer
at it for hours without going blind, or crazy. I plan
to use it for hacking, and I'm inclined to chose the
black and white monitor instead of the color one, to
save my sight. I'd appreciate opinions of those with
"hands on" experience. How does the B/W one compare with
the Mac's?

I was also thinking on getting an Epson F85 printer.
Does this make sense? Does Atari offer any good printer?

I'll post useful replies.

Quick Question:

Does the Atari 520ST have video display circuitry or is the 68000 bogged down
hopelessly like the Macintosh? I have this friend that keeps bugging me, say
that the cpu will be operating at only one third of its full capability,
because of the need for video refresh, etc. Hearing "Its processor is as slow
as a Mac" is making me get homicidal <heavy breathing, flared nostrils,
clenched fists!> :^)

And a few more questions:

Does TOS (or whatever the OS is called) support the same, standard prompt-based,

line-oriented interaction as do UNIX and MS-DOS and CPM? Or am I going to be forced to use the GEM metaphor (ugh!). I much prefer sitting there looking at a prompt and seeing the screen scroll for most of my work.

Much Thanx,

The nice thing about Action! is that the basic system, everything you
need, is right there in the cartridge. You don't fool with the disk
in your edit,compile,test cycle. I'm pretty sure I bought the "toolkit"
(or whatever it's called) and I don't think I ever needed it.

Now a commercial.

Action! is quite wonderful. If you use your 8 bit Atari for any sort of
program development, even simple things you might ordinarily do in BASIC,
you will be impressed by Action! In fact, when I compare it with the comparable
tools for software development on UNIX, MS-DOS, VM/CMS, Mac/HIPPO; Action!
continues to amaze me with its balance of simplicity, useability, and power.
Really a great product.

Now when will ST Action! be available?

sorry if this is a repeat message for you.

This is probably ancient history, but does anyone know the origin of the
word "Byte"? Why the "y" ? (pardon the pun). I seem to remember some
relationship to the word "Bit", but beyond that my mind's a blank.

I got the disk and a copy of the manual free from my dealer.
All dealers should now have this stuff, but if yours doesn't, Atari
will mail you the disk & docs after you return your warranty card.

RE:
"Again, I have to ask a question previously asked by another: who is "we"?
I have never heard of CDY Consulting"

Try looking in the current issue of ANALOG (or was it ANTIC?). I think
they have a full page ad in there.

If it is the company I'm thinking of, they sell a monitor rom that
replaces the one in the ATARI. The two magazines have said it is
extremely useful.

They also sell a floating point rom replacement, FASTCHIP. I don't
know if they just sell it or if they made it. After my first game
of 'Rails West' last week, I'm almost ready to order it.

>
>   Adolfo

Adolfo, I was up in LA for T-day and found that Priority One Electronics (in Chatsworth, mind you) had both the Atari 520ST and the Amiga for sale. I decided to go see them side-by-side. Overall, I might get the Atari, but that's not the point.
Flame on
They had the Atari for what appeared to be $100 off list price, but beware tricky ads. $499 w/o monitor, but the ad doesn't mention that you *have* to buy the monitor. OK, monochrome $199, for a rough total of $698, $101 less than list $799. color $399, for a total of of $898, $101 less than list $999. But then the !#$%!!! salesperson tries to tell me that the price doesn't include the disk drive. I calmly inform this person that the Atari includes the disk drive (ad says $199 for additional disk drive) and try to move onto other issues. Person insists, "No disk drive." I try to find ad in INFOWORLD to say, "see"! No magazine. Finally, I leave in disgust. The salesperson was saying "Come on Monday, we'll know then." What, do they get smarter after the weekend? ARGH! I even had to advise someone else in the store that what the salesperson was pushing for them wasn't what they needed. It's business like that that is responsible for the disillusionment with the computer industry and the recent market downturn. Nobody in the store could even answer simple technical questions about either the 520 ST or Amiga. (note: the Amiga also seemed approx $100 cheaper than list.)
Flame off

The question is, should you buy there once you know what you want, and take advantage of their cheaper prices, or avoid like the plague?
(I am assuming that someone like the manager would, with some effort, be able to ascertain that the machine does come with the disk drive.)

(You may be sorry you asked!) There is quite a bit you have to know to read thejoystick/mouse ports. If you don't want to read all of this, look for part 2 of this document - I'll include a sample source listing to show you how to do it.

Both the joystick port and the mouse port are controlled by the "Intelligent Keyboard" (ikbd) which (quoting Atari's documentation) "communicates with the main processor over a high speed bi-directional serial interface...", and, "...can function in a variety of modes to facilitate different applications of the keyboard, joysticks, or mouse."

Keyboard

The keyboard always returns key make/break (press/release) codes. The break (release) codes are obtained by ORing 0x80 with the make (press) codes. The key codes are defined as follows:

Code	Key	Code	Key	Code	Key
00	undefined(?)	10	Q	20	D
01	ESC	11	W	21	F
02	1	12	E	22	G
03	2	13	R	23	H
04	3	14	T	24	J
05	4	15	Y	25	K
06	5	16	U	26	L
07	6	17	I	27	;
08	7	18	O	28	'
09	8	19	P	29	`
0A	9	1A	[	2A	LSHIFT
0B	0	1B	]	2B	\
0C	-	1C	RET	2C	Z
0D	==	1D	CTRL	2D	X
0E	BS	1E	A	2E	C
0F	TAB	1F	S	2F	V

Code	Key	Code	Key	Code	Key
30	B	40	F6	50	DOWN ARROW
31	N	41	F7	51	{not used}
32	M	42	F8	52	INS
33	,	43	F9	53	DEL
34	.	44	F10	54	{not used}
35	/	45	{not used}	55	{not used}
36	RSHIFT	46	{not used}	56	{not used}
37	{not used}	47	HOME	57	{not used}
38	ALT	48	UP ARROW	58	{not used}
39	SPACE	49	{not used}	59	{not used}
3A	CAPS LOCK	4A	KEYPAD -	5A	{not used}
3B	F1	4B	LEFT ARROW	5B	{not used}
3C	F2	4C	{not used}	5C	{not used}
3D	F3	4D	RIGHT ARROW	5D	{not used}
3E	F4	4E	KEYPAD +	5E	{not used}
3F	F5	4F	{not used}	5F	{not used}

Code	Key	Code	Key
60	ISO KEY	70	KEYPAD 0
61	UNDO	71	KEYPAD .
62	HELP	72	KEYPAD ENTER
63	KEYPAD (		
64	KEYPAD)		
65	KEYPAD /		
66	KEYPAD *		
67	KEYPAD 7		

```
      68   KEYPAD 8
      69   KEYPAD 9
      6A   KEYPAD 4
      6B   KEYPAD 5
      6C   KEYPAD 6
      6D   KEYPAD 1
      6E   KEYPAD 2
      6F   KEYPAD 3
```

Mouse

There are 3 different ways ikbd can report mouse motion:
relative, absolute, and by converting mouse motion into cursor control
key equivalents. The mouse buttons can either be treated as part of
the mouse or as additional keyboard keys.

Relative Position Reporting:
When a mouse event (mouse button pressed or released, or motion in
either axis) occurs, ikbd returns a three byte record containing:

```
    %111110xx ; mouse position record flag
           ||
           |------- ; right button state
           -------- ; left button state
    %xxxxxxxx ; delta X (twos complement integer)
    %xxxxxxxx ; delta Y (twos complement integer)
```

NOTE - ikbd may return more than threshold delta X or Y since no
relative mouse motion events will be generated during certain
operations. Also, if the accumulated motion exceeds +127..-128, then
the motion is broken into multiple packets.

Absolute Position Reporting:
Commands exist for reseting the mouse position, setting X & Y scaling,
and interrogating the current mouse position (see below).

Mouse Cursor Key Mode:
ikbd can translate mouse motion into the equivalent cursor keystrokes -
the number of "clicks" per keystroke being independently programable in
each axis. Mouse motion produces the cursor key make (press) code
immediately followed by the break (release) code for the appropriate
cursor key. The mouse buttons produce scan codes above those normally
assigned for the largest envisioned keyboard (i.e. LEFT=0x74, RIGHT=0x75).

Joystick

As in mouse reporting, ikbd can report changes in the joystick
state in several different ways: joystick event reporting, joystick
interrogation, joystick monitoring, fire button monitoring, and
joystick key code equivalents.

Joystick Event Reporting:
ikbd will generate a record when the joystick undergoes a change of

state (i.e. when pressing forward, pulling back, or pressing the trigger). The event record consists of two bytes:

```
%1111111x ; joystick event marker
        |
        ------- ; joystick number (0 or 1)
%x000yyyy
 |   ||||
 |   ---------- ; stick position
 -------------- ; trigger
```

Joystick Interrogation:
The current state of the joystick ports may be interrogated at any time by sending the "Interrogate Joystick" command (see below) to ikbd. The response is a three byte report:

```
0xFD     ; joystick report header
%x000yyyy ; joystick 0
%x000yyyy ; joystick 1
          ;  where x is the trigger
          ;  and yyyy is the position
```

Joystick Monitoring:
It is possible to devote nearly all of the keyboard communications time to reporting the state of the joystick ports, at a user specified rate (see below).

Fire Button Monitoring:
A mode exists which permits monitoring a single input bit at the maximum rate permitted by the serial communications channel. ikbd monitors joystick 1 and packs the data, 8 bits per byte for transmission.

Joystick Key Code Mode:
ikbd may be commanded to translate the use of either joystick into the equivalent cursor control keys. Joystick events produce the make (press) code, immediately followed by the break (release) code for the appropriate cursor motion. The trigger produces key scan codes above those used used by the largest keyboard envisioned.

Power-up Mode
---
ikbd performs a number of self-test diagnostics on power-up. If no erros are detected, the code 0xF0 is returned. (Actually, depending on the version, you may get 0xF1, 0xF2, etc.) ikbd defaults to mouse position reporting with threshold unit of 1 in either axis, and the Y=0 origin at the top of the screen, and joystick event reporting mode for joystick 1, with both buttons being logically assigned to the mouse. After any joystick commands, ikbd assumes joysticks are connected to both joystick ports. Any mouse command (except "Mouse Disable") then again causes port 0 to be scanned as if it were a mouse, and both buttons are logically connected to it.

ikbd Commands

Commands may be sent to ikbdws using the Ikbdws() function (ikbd Write String):

```
VOID Ikbdws(cnt,ptr)
WORD cnt;     /* number of bytes to send minus 1 */
LONG ptr;     /* pointer to the string of bytes  */
```

Reset - return ikbd to power-up state

```
    0x80
    0x81
```

Set Mouse Button Action - select mouse button mode

```
    0x07
    %00000mss ; mouse button action
          ||| ; (m is presumed to be 1 when in
          ||| ;  Mouse Keycode mode)
          --------- ; 0wx   mouse button press or release
              ;  ||     causes mouse position report
              ;  ||     (wx only relevant if in
              ;  ||    absolute mouse pos. mode)
              ;  |--    1 -> mouse key press causes
              ;  |          absolute pos. report
              ;  ---  1 -> mouse key release causes
              ;          absolute pos. report
              ; 100 = mouse buttons act like keys
```

Set Relative Mouse Position Reporting (default)

```
    0x08
```

Set Absolute Mouse Positioning

```
    0x09
    Xmsb     ; X maximum (scaled mouse clicks)
    Xlsb
    Ymsb     ; Y maximum (scaled mouse clicks)
    Ylsb
```

Select Mouse Keycode Mode

```
    0x0A
    deltax        ; distance in X clicks to return
    deltay        ; distance in Y clicks to return
```

Set Mouse Threshold

```
    0x0B
    X        ; x threshold in clicks
    Y        ; y threshold in clicks
```

Set Mouse Scale

```
     0x0C
     X        ; horz. mouse ticks per internal X
     Y        ; vert. mouse ticks per internal Y
```

Interrogate Mouse Position

```
     0x0D
returns:  0xF7     ; abs. mouse pos. header
          %0000xxxx; buttons
               ||||
               |||------- ; right button down
               |||        ; since last interrogation
               ||-------- ; right button up since last...
               |--------- ; left button down since last...
               ---------- ; left button up dince last...
          Xmsb     ; X coordinate
             Xlsb
          Ymsb     ; Y coordinate
          Ylsb
```

That's about all I have time for now. I'll finish up the list of commands, and give an example (in C source) of how to put all of this together in a couple of days.

I just got a mailing from Computer Mail Order in Williamsport, PA.

They're offering all sorts of deals on an awful lot of hardware and software for the eight bit Atari line, including a lot of third party interfaces, modems and printers.

Interestingly, they're also offering some ST stuff, so I guess they've reconsidered their decision to discontinue carrying Atari's line. Their prices on the 520ST are $699 for monochrome and $799 for color.

I've dealt with these people in the past and have had only positive experiences. As mail order places go, they are among the more professional.

January 1986 ANTIC TOC
Theme: Atari Products Are Back!

Page Article

11 ANTIC ONLINE
    A discussion of the new features of SIG*ATARI on CompuServe (see separate article).
12 COMMUNICATIONS: SYSOP SANTA CLAUS
    A selector program that organizes the gift possibilities for someone on your list. You use this program to search a vast gift database on CompuServe. You can also get the gift database on disk from ANTIC.
14 MAPPING THE XL/XE
    An article by Ian Chadwick, author of _Mapping the Atari_. He has been added as a Contributing Editor of ANTIC.
18 DANDY DISSOLVER
    A BASIC program that allows you to "dissolve" pictures using all kinds of special effects.
21 DUNGEON MASTER'S APPRENTICE

This program stores all your characters and their abilities on disk, rolls multi-sided dice and calculates confrontation damage. Makes a dungeon master's job much easier.

23 APPOINTMENT CALENDAR
A cleanly programmed, useful personal appointment calendar.

25 ATARI BINGO CALLER
A random number generator that brings your bingo games into the computer age.

29 FEATURE REVIEW: TWO HOT NEW MODEMS
A review of the Code-A-Phone Tel-A-Modem (300/1200) and MultiTech MultiModem (300/1200). These list for $599 and $499 respectfully.

33 FEATURE REVIEW: BASIC XE FROM O.S.S.
ANTIC calls BASIC XE the ultimate BASIC for the 8-bit Atari's. One special feature, EXTEND, allows you to make use of the extra 64K of memory in the 130XE from BASIC.

38 PRODUCT REVIEWS
Software:
Kennedy Approach (MicroProse Software)
Halley Project (Mindscape, Inc.)
Wishbringer (Infocom, Inc.)
Mindshadow (Activision)
Twirlybird (Hardwood Software)
Objective: Kursk (S.S.I.)

45 GAME OF THE MONTH: WIREBALL
You'll feel like Spiderman as you shoot wires to zap your creature around the screen, eating dots and escaping the deadly touch of enemies. BASIC.

48 ST FONT LOADER
An introduction to the built-in fonts of the 520ST and a program to create you own. ANTIC's C listings are written in Alcyon C which is included with the developer's kit.

57 ST LISTINGS ON MONTHLY DISK..AND HOW TO GET THEM
All of ANTIC'S ST listings are on their monthly disk and they can be ported to the 520ST if you have an 8-bit Atari, a null modem and an XMODEM file transfer program. This article tells you how.

59 ST-WARE FROM TWO CONTINENTS
This is the ANTIC article that was downloaded from CompuServe to Netnews a couple of months ago.

68 NEW! FOR YOUR ST FROM ANTIC SOFTWARE
A listing of 7 programs now available. They are:

ST201 C.O.L.R. Object Editor ($29.95): An all-purpose graphic design utility package for ST program designers using 16-color mode.
ST202 Maps And Legends--The Cartographer ($34.95): This package includes a library of world maps and built-in coordinate finder. Create your own,print & save.
ST203 Murray And Me ($34.95): See below.
ST204 Mom And Me ($34.95): These two programs from England

are living, computerized, interactive cartoon characters that utilize the memory and graphics ability of the ST to create artificial personalities. (Monochrome only)

ST208 Desk Diary ($19.95): Never forget those important phone numbers and meetings again. Monochrome only.

ST209 Lands Of Havoc ($19.95): An arcade speed graphics adventure game in full color (also works in momochrome)

ST210 Mission Mouse ($19.95): This jump-and-climb game had unique high-res graphics, 25 levels. (monochrome)

71 TOS ROADMAP
A discussion of how GEM and TOS work together to produce a user friendly computer.

75 ST PRODUCT NEWS AND REVIEWS
Software:
HEX (Mark of the Unicorn)
CHAT (SST Systems)
Express (Mirage Concepts)

83 SOFTWARE LIBRARY
The program listings for all the articles are listed here.

105 NEW PRODUCTS

COMMENTS: In the editorial page, ANTIC reported the results from over 400 readers that answered their questionaire. Although 15% of these already own 520ST machines, ANTIC stated they will never turn away from the million plus 8-bit Atari owners. Several new companies are advertizing ST software. One of the most expensive is The Graphic Artist by Progressive Computer Applications that turns the ST into a CAD type work station. At $495, it isn't going to be a big seller to the casual user. O.S.S. has an ad for their first software for the ST: DiskKit, Pascal and Prolog. Til next month...

> and I (ex of Sun, now independent) have been saying:
>
> "Don't use the top byte of a 32-bit address as anything but a piece of
> the address..."

I don't want to rekindle the whole discussion, but I thought I'd put in
the other side of the argument, at least as it existed in net.arch:

  "Use the top byte of a 68000 address for something else (like the type of
  the object pointed to) if this is sufficiently important to your application
  that it's worth sacrificing expandability of memory past 16MB. Don't
  be surprised if this isn't very portable to other 68000 systems."

I don't advocate this usage just to save 10% on data space for your
program. It's more for something like a Lisp interpreter where tag bits
can greatly enhance performance and implementation simplicity. You ought
to be prepared to think of the processor, not as a 68000, but as some
new micro with a 16MB address space and nifty typed pointers.

Another reminder that D E C E M B E R 2 0 T H will see the first meeting of the Jersey Amiga Users Group (Jaug). We will be meeting in the large lecture hall of Hill Center, Rutgers University in New Brunswick, N.J.

The meeting shall begin at 7:30. Representatives from several manufacturers and retailers are expected to attend and will be making special ``user-group'' discounts available. AmigaWorld may also attend, if not in person, at least in the form of sample copies of the mag.

For directions to Hill Center, call the Rutgers Microlab at (201) 932-3129. For more information, talk to my grandfather at (201) 271-4522 (treat him nice and do what he says).

Net.atari readers are of course welcome as are memebers of the interested public.

Perry

I've been playing with a ST loaned from ATARI for this week, including
the developer's kit. Having a lot of fun breaking the C-compiler,
finding out that the vt52 emulator only works so-so, benchmarking,
the usual stuff. The machine clearly has a huge amount of potential
waiting to be mined. The problem for me is that I need a good
terminal emulator with graphics right now to make the buy (we're
talking 6 or 8).
Since initially we will be running these guys under UNIX we don't
care if they are vt100 emulators or whatever, so long as they have
standout mode, clear screen and cursor motions. As for graphics, we
are fairly device independent through an extension to termcap/terminfo,
and can run Tek graphics, HP, anything sensible. So far I haven't
managed to track down a good terminal emulation program. I would be
pleased with any of the PC programs such as PC-LINK III. Any leads?

After monitoring the raging debate on various and sundry bouncing ball programs,
I realize that my 520ST will not be complete until it has a bouncing ball
of its own. If anyone has it, could they send it to me?

You'll have to tell me how to handle the binary file (unless you have
C source)

Also, I'd be happy to be sent any other public-domain programs (I have no pride)

My mailing address (CSNET) is

terrell@ohio-state

Thanks in advance,

Eric Terrell

Although the hippo-c compiler from haba is one of the few compilers out for
the 520ST, I would strongly urge anyone interested in getting a compiler
to wait for others to hit the marketplace.

hippo-c is copy protected (which is insane for a compiler)! The manual says
that one can copy the files to another disk and use it, as long as the
original is in disk a. While this is true, for a single drive system,
one is obliged to use the original disk for storing program files, etc.

Although the manual gives one the impression that hippo-c is a full
K & R C comiler (except for floating point) I had great difficulties
getting some of my C programs compiled with it. A was able to compile
a trivial one. When I tried to compile a somewhat longer program
(about 400 lines) I got the fatal error "out of registers." Nowhere
in the manual is there any mention of why it ran out of registers. I felt
like screaming "then use !@#$!@#$ main memory!"

The icon - based user interface of GEM really appeals to me. The hippo-c
compiler does not use this interface and instead has a pseudo UNIX
interface. I would much have preferred to use icons and the mouse,
even though I use UNIX all the time.

So to sum up, unless you are VERY desperate for a c compiler and are willing

to settle for a copy-protected compiler with nontrivial bugs and an unsatisfactory user interface, don't get it. (I'll be happy to sell mine).

 Yes, indeed. There are floating point routines in the ACTION! tools diskette, as well as a PRINTF routine (a la C) and a few other little items that I can't recall. Never really had much use for the floating point stuff....such a relief to use integer arithmetic after dealing with Atari BASIC for so long.

AT LAST, solid information from an unbiased source! Is it true that Commodore told the bank that the check is in the mail? :-)

After waiting for someone to step forward, I have taken the plunge. I will take over as moderator of INFO-ATARI. It may take several weeks for me to learn how to use TOPS-20 (again), so please be patient.

I would love to to help me.

Funny how Commodore never mentioned how easy the bouncing ball is to do, the
major problem being the actual data to do the colour table animation on (and
that's not really a problem). Since the animation just involves changing
a few registers every few frame times there is plenty of processing power
left over. Synchronising sound is just a matter of saying "well gee I'm
on frame X, lets make a noise". Note that the fact that the ST was doing it
faster implies nothing about the power of the machine

Let's stop the demo war discussion, at least at the level of "well yes you
can do it but you had to work harder to get it done".
Marketing hype is marketing hype, the ST and the Amiga are different,
each with their own advantages and disadvantages depending on what your
needs/budget are. If you want real graphics power, buy an Adage/Ikonas.

Personally I own an ST, but believe that GEM sucks and that TOS should be
tossed (a 200K OS - good grief!) but it provides me with a cheap bit-mapped
display, a 68000 and lots of support hardware which can be used for other
purposes (like a real-time, message-based OS).

In the most recent issue of Analog magazine, there is a program
which uses scan-line driven interrupts to produce a display with
256 or 512 colours on the screen at once. The author claims to have
found the correct colour shadow registers and line-driven interrupt
information by trial and error. Does anyone know of documentation
on how the st hardware displays the screen? In particular
is it possible to do hardware driven scrolling by modifying
the hardware physical screen base at the end of each
scan line drawn?

Nobody is denying that the bouncing ball demo is more impressive looking than
difficult. A recent message placed the Atari developement time at approx.
one week also. The basic thrust of Atari's marketing is not "we are better
than Commodore" but "we can do much of the same stuff they can, cheaper".

Before the Atari-duplicate demo, the Commodore people were so proud of
themselves....now they are saying "it was nothing anyway". Make up your
minds!!!

     No there isn't a lot there for Atari people yet. If the readership builds, then we can expect that there will be. Keep in mind that much of what's put into 68 Micro J. comes from us readers. As such, what they're waiting for is submissions as well as subscribers. If you have something to share with others, then 68 Micro could be a nice vehicle because it tends to be more open and less biased (notice how *many* different systems are already supported?). A lot of high tech'ers are not on and probably never will be on Usenet. BIX and CIS can be too expensive as well. Good magazines are cheaper and reach more people.

                                        Cheers -- Jim O.

     Guys, this is *not* a flame. It's just an observation. If you keep reinventing wheels at this rate, you'll never get anywhere. Is this by any chance compatible with the any of the hundreds of other Hexbin/binex programs around? I don't recognize the format myself but if it isn't then why not? The protocols are easily obtained and no secret. The programs aren't much harder to write. Why not try for a bit of compatibility?

For Amiga: (not my organization, not inpartial)
1) You can define your own character sets.
2) The speed is comprable to the built in rom sets for characters of
     about the same size and shape (fixed pitch)

3) any size font is allowed.
4) partial fonts (<256 characters) are allowed and encoraged.
5) to output text in your font you:
     AddFont(texffont);
     OpenFont(textatribute);
     Text(rastport, string, chat_count);

A font editor is not yet available from Commodore-Amiga.

How about using uuencode, the reciever can use uudecode on the unix machine
he is connected to (or write a simple uudecode routine), then use kermit
or xmodem to download from the local host.

A very good friend and hacking partner of mine was at a computer and electronics
swap meet in the San Francisco bay area, and he saw a dealer selling 1450's.
They were not functional, and were being sold for parts. The claim was that
they could be made functional with "some" work.

I may be able to find out more specifics on who/where/how much. If there
is enough interest, I will contact my friend (he's not on the net, and now I
live in N.Y.).

May I suggest writing uudecode for the atari as well? The actual code

should be fairly simple (longs printed out base 96) it is important to
be sure that the byte order is preserved (msb to lsb) which is less of
a problem on a 68000 than on an 8086 or VAX.

The documentation is in the UNIX manuals. Sure beats using hex format.
Compression is 4/2 rather than 2/1 meaning less traffic.

Format (discussed in detail in uudecode(5)) is basicly.

```
------------------------------cut here---------------------------------
/*
     this is an approximation of the encoder from which a
     decoder can be written
*/
uuencode(FileName,*infile)
char *FileName;
FILE *infile;
{
     long xbuf;
     int i,j,count;
     char bytarr[64];
     litbuf[5];
     printf("\nbegin .%s\n",FileName);
     while(count=fread(bytarr,1,62,file)!=EOF)
     {
          printf("%s",count+' ');  /*count between 0 and 64*/
          for(i=0,i<=count,)
          {
             xbuf=0;
             for(j=0,j<3,j++) /* pack next three bytes into long */
             {
               xbuf+=xbuf<<8+bytarr[i++]; /* this prevents "flips" */
             };
             for(j=0,j<4,j++) /* push out as printable chars */
             {
               litbuf[4-j]=xbuf%96+' '; /*insures value is printable*/
               xbuf%=96;
             };
          printf("%s",litbuf);
          }
          printf("\n"); /* this is the end of one line */
     }
     printf("end\n");
}
```

I'd write the decoder, but I'm out of time. This routine is not debugged
dress up the interface a little and post it back. I am using vanilla
K&R because I haven't got the ST yet. I would be interested in seeing
what won't compile, or what "extras" are needed.

About a month ago I came across an add for BG MICRO that advertised a modem board (300 baud) for the atari computers. they were "as is", and they were selling a few of the microprocessors that went with them, an 8000 series that has eprom on the processor chip. I bought the board and the processor for about $20 total investment. I figured it was worth the gamble. Well, I pluged in the processor chip and turned the power on, and all I can say is that an led sure enough lights up, whatever that means. Here is what I know or suspect about the board.

1. It is made byd Racal Viadic
2. It is direct connect, and works off of the ATARI serial port. You do not use this in conjunction with the 850 module.
3. I suspect it to be an ATARI 1030 modem.
4. It (probably) needs some software drive it, and I have heasrd that the 1030 does come with some software. In any case, the standard R: driver wont work, as it is just an rs232 driver that works on the 850 port.

What are my options? Well, if I knew what it was expecting in the way of serial bus commands, I could write my own driver. However, as I have no documentation, this would be a difficult task. I would basically have to treat it as a black box, and send every posible sequence imaginable down the serial bus, and try to monitor its response untill I got the desired action. (desired action=connecting to phone line, sending/receiving data)

BUT! If some kind person out there thinks that they know from the above description what kind of modem this is, and could forward ANY info to me, I might have a fighting chance.

OR, (better yet) if someone has some software that they think would work, I would be more than happy to send a diskette in a prepaid mailer! In any case, please contact me with any useful info.

I have been a quiet subscriber to net.micro.atari for the last several
months. I will add my two cents to the fray. I do think it would vbe
a good idea to split the list. I have an old 800, and find it bothersome
to have to read through all the ST stuff for 8 bit info. On the other
hand, I am very interested in the ST line, and would probably be on
that list as well. But when I want to read the thinhat really matter
to my 8 bit system , I don't want to have to read throught all the
ST trivea. But, this is all academic, because last time I heard,
WE ARE STILL WITHOUT A MODERATOR FOR THE EXISTING LIST!!!
HOW CAN WE "SPLIT" THE LIST WHEN WE DON'T KEVEN HAVE A MODERATOR FOR
THE EXISTING ONE?? SOMEONE PLEASE TAKE OVER THE JOB.

Correct me if I am wrong and someone has already done us this kind service.

> Line "A" Manual
> Programmable Sound Generator
> MicroEMACS Screen Editor Tutorial

i.e. for $300 you get C, an assembler, a linker, MicroEMACS, and a guide to GEM and the BIOS so you can get your sticky little fingers onto all the system routines.

I'm eagerly awaiting mine (I ordered it at the same time as I ordered my ST).

I just bought the Unix-like "Micro C-shell" for my ST. The package includes a shell and some Unix-like programs. Major features of the shell include stdin and stdout with redirection and pipes, shell variables, aliases and history substitutions, and shell scripts.

Commands include cc (requires the Digital Research compiler), cmp, diff, grep, sed, ls, more, lpr, pr, wc, cat, cd, chmod, cp, mv, df, echo, mkdir, and set. Of course, some of these are built in and some are separate programs.

These are not ports of Unix tools, but rather rewrites. All the most

common features and options seem to be implemented, with the less common ones omitted.

I'm generally pleased with the tools provided, but I do miss some things like 'make'. They tell me that they are working on a version of make to be sold separately. The tools make life much nicer for Unix-types, but of course it is not like real unix. But I'd still recommend the package highly. It is available for $49.95 + $5 shipping + CA tax (if any) from:

Beckemeyer Development Tools, Dept. RN
592 Jean Street #304
Oakland, CA 94610

I'm not associated with the above company in any way, so my comments should be unbiased. If you do write them please put the "Dept. RN" on the address -- I told them that there would probably be a lot of interest in net-land, but they doubted that anybody with a VAX or PDP-11 would have an ST. They have agreed to count the number of letters with "Dept. RN" in the address just for fun.

Cheers, and happy 'grepping',

--Bob

>for anyone else to run your Action! programs.
>

>... [C]ould somebody with an Action! package confirm or deny this?

Yes, you either need the cartridge or the run-time package (~ $30.00).
I'm working on a program in Action! which adds the run-time package copied
from your cartridge to the end of an Action! executable, and patches all the
calls to the run-time library. This project has a somewhat low priority,
but I should get it finished by the end of the year. I'll either put it in
the public domain, or sell it to Analog. Don't see how you could have come
up with a price of $99 for the Action! cartridge, I got mine for $59.00.
Shop around!

David:

     I tried to send you mail, but it didn't work. I have some
questions that I can't find the answers to.

     First, I have both OMNIMON and OMNIVIEW.

     Second, Could you send the lit on the 800XL upgrade? Send
it to :   C. E. Malloy, III
          AT&T Bell Labs
          Warrenvill & Naperville Rds.
          Room: 3D-208
          Naperville, Ill

     Third, I use the Chameleon program from APX to logon to Unix from
home. How do you get the program to work in 80col mode with OMNIVIEW? I
have tried every thing that I can think of and nothing is working. Please
help.

RE: HAPPY upgrades.

Would someone pleased with the Happy upgrades explain why? Why
would you want to upgrade a 1050 when an Indus drive is about $200?
Wouldn't you be better off buying something else in the first place?

If I were to buy the upgrade for my 1050, what improvements could I
expect?

 James Omura suggested the use of the Motorola S1 format for
 transfer of binary files.  This will work fine as long as the
 file is 64k or less.  Of course if it is greater than 64k it
 probably is too big to send across the net anyway.  The following
 programs were written by Budd Pass and can be used to load and unload
 binary files.  They were written for the 6809 but are also in use
 on several flavors of UNIX.  You may use these progams if you desire,
 but no responsibility is assumed or implied.  Any comments found in them
 are personal and can not be construed as either support or non support
 of the various opperating systems or anyone else alive or dead.

Summary: S-record formats have been extended; but please don't post binaries.

Jim Omura posted a visual description of the Motorola S-record
format.  You might note that it didn't support addresses longer
than 16 bits, relocation information, etc.  Motorola has extended
```

this format with different record types for longer addresses and
such. If you use S-records on a 68000, please find out and use
the extended format.

But, please don't post any binaries, in S-records or any other way.
(This is my personal opinion, you are free to ignore it. I think
until the net resolves that it either wants binaries or doesn't,
it would be an inflammatory thing to do, though.)

When I saw an Atari 1030 modem operating recently, I realized that my
bigest objection to AMODEM was the lack of word wrap. The 1030, like
AtariWriter and other word processors, does not merely wrap around from
one line to the next in the middle of a word, but rather backs up to
the nearest preceed space which is converted to a CR.

I usually use VT10SQ as my terminal program, but have to switch to
AMODEM for FTP. I considered working on AMODEM to provide word wrap,
but decided that since the terminal-handling code is assembly language
encoded in character strings that was too difficult for me.

I would be interested in exchanging ideas with anyone else interested
in this problem. I would be most interested in hearing from anyone who
has a terminal emulator with word wrap and FTP.

Sincerely,

I think it isn't very useful to give the Atari ST group a name like
'net.micro.atari.520st'. It should better be called 'net.micro.st'
or 'net.micro.atarist'. Reasons:

It creates less subdirectories than you want to create. Much news
administrators won't be glad if the tree for net.micro is expanded.
This is also the case for net.micro.amiga and net.micro.mac.

The name suggests this newsgroup can't be read by 260ST or 520ST+
owners. Better choose some general names for one type of micro-
computer.

My opinion is that a newsgroup 'net.micro.st' has to be created
soon!

etc etc etc etc (yawn)

Why is it that Amigaphiles make a big deal of electronic trickery,
when all it can do is pretty pictures, and generate "crash" and "woosh"
noises? Maybe they see it only as a games machine. Juggling bit planes
is no use when you want to display text, or actually do computation
quickly (I refer of course to the recent dhrystone benchmarks).

I accept that architecture of an Amiga allows it to draw a better
bouncing ball, so when I want to draw bouncing balls I'll buy an Amiga.

Nigel

This has been much talked about on Compuserve of late. It has been stated
(bear in mind, Commodore has not commented on this), that they were, uh,
"prevented" from attending by one or more of their creditors due to having
(allegedly) defaulted on some of their debt(s). Seems 'tis the bean-counters
of the world, and their ilk, that ultimately decide the fate of a new product
in the Marketplace ... welcome to "The Real World"!

It is also reported that they *were* there privately. (I just *love* how
the Underground works!)

And it's been said that they won't be exhibiting at CES either for the same
reason ... at least not "officially".

CYA time: The above statements may or may not be true. In either case, they
        are my opinions, and not those of my employer, roommate, or mouse.

/kim

Yes, I am in favor of splitting the group. However, with different names.

My suggestions are:

     net.micro.atari
     net.micro.st

     or

     net.micro.atari.8
     net.micro.atari.16

Commodore was also in the exhibitor guide (Booth B4) at the Canadian

Computer Show in Toronto (Nov 18-21). However the only thing in their
spot was a bunch of chairs. Very nice of Commodore to give tired feet
a place to rest :-). On the other hand Atari was VERY prominent at this
show.

  I think I got the $99 from adding in the cost of the run-time thing. It was
over a year ago that I was considering buying it, so my memory is admittedly
hazy. I wasn't trying to scare anybody away from Action! Honest!
Incidentally, now that I have had a good chance to find out what a royal pain
it is to use either assembler or cheap C "compilers", I'm once again
considering buying Action!. I'd be interested in hearing about the program you
mentioned. I'd also be interested in your experiences with selling it
to Analog, if you decide to go that route.
   One more question I have about Action!: is it a true source-->machine code
compiler, or does it translate to p-code a la Deep Blue C?

I do like the Amig*'s graphics; the Amig* is flashy and flexible, and is
everything I'd want in an Atari 800.

No doubt there will be demo wars. Clearly the Amig* can blow the ST out of the water with flashy graphics, and if the people at Amig* are going to do incredible demos for the next two months, then we know where they're at.

The Amig* has traded flashy graphics for I/O bandwidth. Remember what people used to say about the Mac, before Hyperdrive? How are you going to attach a fast hard disk to the Amig* when it is doing all that video DMA?

The Atari bouncing ball demo was written in about a week by Jim Eisenstein. He wrote a kind of "ball blit" in assembly. He had to count cycles. HORRORS! He did all the development ON the ST, with a hard disk. Where was the Amig* bouncing ball written?

Note, also, that the consumer does not have to count cycles to watch the bouncing ball. I strongly suspect that the ST can at least /come close/ to the Amig*'s graphics. How close is "close enough" for an assembler, or a database manager, or a C compiler? Granted, the ST will probably lose big when you play Hemmorhoids in Space.

How often do you do that?

I expect to have production OS ROMs under my christmas tree. And maybe a blit chip, soldered on top of my 68000 ....

-Landon

 Question :
      Has anyone managed to get a version of xlisp to work for the ST?

 Notes:
      Optimized Systems Software in San Jose is working on a Prolog
      for the ST, due out sometime in January.
      (got this from their phone people)

      Metamaco (sp?) was/is (?) working on a Lisp for the ST.
      Don't know if this is still in progress or what.

 Another Question :
      (I asked this earlier...but the answers were too confused..
      yes/no?)

      Does anyone know if anyone working on Unix for Atari 520ST?
     (Not the next machine, Atari TT, but the ST).

Could you elaborate a little on the blit chip soldered on top of
your 68000? Some of us netters who have upgraded our ST's to 1 meg
are not averse to doing a little soldering.

~~~~~~~~~~back lineater, back!~~~~~~~~~~~~~~~~~~

The story i hear from the usually reliable sources is that Amiga's
new partner (the bank) wouldn't let them go to Comdex or CES in LV
for that matter.

I am 520ST owner, and I just came found out about the 'news' command on
our UNIX system. I am able to read the announcements of the net.micro.atari,
but can I get on any special (electronic) mailing lists?

I am interested in getting any public-domain software, reviews on
software and hardware, etc.

Thanks,

Eric Terrell

I would like to know what business software is available for the 520st
ie: word processor, spread sheet, datatbase, etc. Also, where could I
find a good review of the machine?

Thanks,

Jim Larsen

I want to correct some information. The Libes' are not running M/SJ out of their garage. They are running it out of their basement. I should know - it is impossible to play ping-pong anymore with the production department doing pasteup on top of it. Also, the last time I was home, the room my bed was in no longer looked like my old bedroom but was referred to as the Circulation/Advertising Depts and Administrative Offices. (To complete the picture, the den is the Editorial Dept.)

Though I don't ordinarily read it, I picked up a copy of Creative Computing which ZD just closed. Dave Ahl wrote a very polite editorial considering the situation. He was also quite blunt, however. It was very anguishing to read his own job-wanted ad at the end of his column.

What really galls me is that there are still subscription cards, request for reader response, advertising rates, etc in the magazine, even though the issue cover was marked "collector's item", so they obviously knew months ahead that it would be closed.

Keywords:LOGO

ref: ST LOGO question

     The manual "A Sourcebook for ATARI Logo" that comes with the ST is rather sad. I have been teaching myself Logo, an enjoyable language very reminiscent of LISP, from this manual and LOTS of trial and error. The manual has a number of typos which make the task of figuring out a new (to me) language doubly difficult.

I have reached a total block however with a command called "READLIST (RL)" which is documented on page 45 as:

> Outputs a list that contains a line typed at the keyboard (input must be followed by a carriage return) or read from a data file.

There are also two other commands which can alternatly access a data file (READCHAR & READQUOTE) and one of then (READCHAR) is said to be able to also access "a device"!

The problem?? There is no indication on how to get the input from a data file!! As far as I can tell it always comes from the terminal. I havn't been able to find any other commands which access the disk as a file, except for the LOAD command which causes the named file of procedures to be loaded and defined.

The ability to read (and store!) data would make Logo a useful language for doing some graphing I am interested in.

Thanks in advance for any help you can give.

If you have the development kit C compiler and wish to use the
various uudecodes posted to net - then beware... The putc function
does nasty things with hex 0xA or maybe hex 0xD. It's better to
replace the calls to putc by something which buffers output in a
file and then call the system Fwrite.

This may of course NOT apply to your version of the standard I/O
library.

Before you get too carried away, you might look into the graphics
processor Motorola is making. Its supposed to be a 68000 with
bit-blit capabilities added (i.e. built in). Last I heard they were
trying to get it out real-soon-now.

Keywords: atari800, atariwriter, DOS, disk

I own an atari 800xl with 1050 disks and have been using atariwriter
with DOS 2.5. In dual density mode, new directory entries appear surrounded
by angle brackets once the disk (apparently) becomes more than a certain
percentage full. When this happens, atariwriter cannot find the files it

needs when using the chain command. I have no information on DOS 2.5. Could someone explain what is going on, and how I can get around it.

Thanks,
Rob Stampfli (cbosgd!res)

I am currently using a (borrowed) Axlon Ramdisk(tm) (r) (or whatever).

I would be interested if someone has thought to extend the 256k memory addition (making XLs look like a 130xe + 128k) to the older 800 (no letters)?

Anyone have any info?

Dear Sandra;

I've heard bad reports about the HABA system. The beta test copy of their compiler was full of little buggies. As far as the Atari developers' kit, it includes 2800 pages of documentation, 6 floppies full of software (editor, assembler, CPM-68K, C compiler, linker, object librarian, etc.). I think it's worth the investment.

Bill S.

Has anyone noticed a couple of funnies with the new 130XE computer?

Namely: self-test is still the same old 1200XL pattern. For a computer that never went over too well, it will be remembered fforever as the one that generated the test pattern.

Secondly, altho they do not show up on the keys, you can generate both the { and } marks from the keyboard! To get the { mark, use <CONTROL;> -- to

get the } use either <CONTROL2> or <CONTROL<> keys. (I.e. CONTROL plus ; or 2 or < to get either a { or }.) For some reason you have two choices to get the } symbol. Why they are not marked on the keyboard is anyone's guess.

>
>Ahh, then why not isolate the Mac-specific stuff in a seperate module.
>

That is indeed very doable. I have a version of the Ancient Clisp (by Thomas Duff) that runs on 512 MAC, VMS, and on my PRO-350 (VENIX). [No.. it is not yet distributable. I have to clear it with Thomas first - and more work is needed.]

It is the SAME CODE, except under MAC, the routines
for the user-interface and memory management are replaced with
those more suitable for MAC. (like windows, menus, mouse poll etc.)

Surely, the porting of MAC programs may leave lot to be desired
in terms of interface, but the question is exacly what we are
porting ?? The windows and menus or the *functionality*.

Perhaps it is safe to say that some MAC programmers worry more
about how the program *looks* rather than what it *does*. SIGH.
And I thought the advancement of systems like MAC would clear
away all the interface blues, and let people concentrate more on
the *functionality*.

Btw: there is another side to the coin. SUN has facilities to
build interfaces to programs that are originally written to run
on ordinary terminals. Check out the ancient UN*X chess running with
such an interface. Does any MAChack need a better hint ???

<line-eater>

To all hardware hacks out there who have opened their 520ST's,

Has anybody identified the four in house chips on the board?
In particular, what are the particulars of the DRAM controller chip?
Is it just that or is it an MMU also? I REALLY WANT/NEED this information,
the sooner the better and am quite willing to sign non-disclosure agreements
etc. if necessary (BIG hint to anyone from Atari that may be listening).

Many multitudinous thank you's from the bottom of my parts bin.

Anxiously awaiting any and or all replies,

How fast does this port operate? How fast can I execute an Interrupt-
Write cycle or an Interrupt-Read cycle from memory to the port?

>IBM's coming line of 386 machines should show us a thing or two...so they
>say. me, i don't know the chip; what do you hackers say about the reputed
>"next revolution" in processors?

     Gee. They're only 1 or 2 years behind (68020 machines are already
on the market including Motorola's own 'Benchmark' and Gimix's 68020
OS-9 and Uniflex single board computer and their SS-50 bus 68020 systems--
these latter 2 machines run Virtual Memory versions of Uniflex or a
more "Standard" OS-9 68K. At Comdex they were running Sculptor and
impressed a lot of people with their speed--oh, and of course Unix
is already available for the 68K's). ;-)

                                    Cheers! -- Jim O.

Subject: Help with MPP1000E Modem
To: info-atari@su-score-arpa

    Help, is there anyone out there with experience with the MPP1000e Modem
for the Atari? I have problems with both uploading and downloading from the
DEC 20 (The only machine I've tried this with). The handshaking looks good,
but the DEC keeps asking for a retransmit of the first block of data. Also,
the 80 column emulator doesn't do anything except cause my screen to black
out.

                    Thank You,
                    Phil Paone

When I bought my 520ST a few days ago, I discovered that a BASIC interpreter
was not included on the language disk. Atari's advertising of the 520ST
mentions that BASIC is included in the system - so how do I get a copy of
the BASIC interpreter and the associated documentation?

Also, can anyone recommend any magazines that have articles about the 520ST

Thanks,

Eric Terrell (CSNET ADDRESS terrell@ohio-state)

This issue came up in January in net.micro.mac; now that we have a
new crop of people writing for a new crop of machines, let me reiterate
what Dale Luck (of Amiga), Rob Warnock (ex of Fortune, now independent),
and I (ex of Sun, now independent) have been saying:

"Don't use the top byte of a 32-bit address as anything but a piece of
the address. I saw the IBM 360 folks get burned by it and don't intend
to let any enterprise I'm associated with do it again. This kind of
usage does NOT automatically break when you install a 68020 (the way it
did in the IBM systems), since 24-bit addressing is not part of the
instruction set (it was defined as 32 from the start). Instead, it
breaks if you ever hook up more than 24 address wires to any 68000
family member (eg 68012, 68020) that brings these bits out to pins. It
DOES decrease cache performance in the 68020, since the same piece of
code can be accessed at addresses which the cache thinks are
different. In a machine with a data cache that doesn't deal well with
aliasing, it could also cause incorrect results. (Data caches are
often used to get maximum speed out of e.g. 20MHz 68020s)."

This whole topic has previously been discussed in net.micro.68k.

The CSA/Amiga board is a great example:
> >Well, the 68020 puts out all 32 bits. But does the system use them? If
> >it doesn't, then it should be ok to play games with these bits.
> CSA's amiga/68020 board has 256k of memory. It was configured to be
> at 7f000000-7f03ffff. This caused a hickup in one of our libraries since
> it was internally using some of the 8msb as some flags. That got changed
> REAL FAST. We advise all those that wish to write software that is
> hoped to run on compatible but more powerful products to assume that all
> pointers are 32 bits.

Sun-3's check to make sure you aren't using any of those bits, so that
when larger models come along (currently 256MB address space, but there
are four whole unused bits up there!) any software that now runs won't
break. Happily, few folks writing Sun-2 software had screwed this up,
so much of it runs on Sun-3's without trouble.

Probably the Amiga really does depend on all those unspecified delays.
When you're trying to cram 3 RAM cycles into every CPU memory cycle, you
use all the kludges you can...

In any case, it should be possible to run a 68020 at exactly twice the
standard clock rate of the Amiga (or any other 68000 system). This
would make the interface synchronous to the rest of the Amiga board and
you could tune the timing of the various signals to match what the
Amiga expected. Given that a 68020 cycle would take 3 new-clocks and a

68000 cycle would take 8 new-clocks, there's plenty of time to fiddle
with generating all the right fake strobes. If you took the time to test
it on all of them, you might even be able to build one piggyback board
that would run in a Mac, Atari, or Amiga, by emulating the 68000 timing
exactly enough.

> I've not worked with 680x0's until now ... is also possible to run a 68881
> with a fast '020 (I don't *think* fast 881's have been announced yet)?

You can run the 68020 and 68881 on totally independent clocks. It uses
standard (wait for DTACK) bus cycles to talk back and forth.

I too am interested in all of the above -- I have deleted over 50% in the

interests of brevity. I am interested in converting a 1200XL, 800XL and a 130XE all to 256K. That's correct, since it only has a 90 day warrenty which is almost up, why not upgrade the 130XE to 256K also!!!

Please add me to any mailing list.

*** REPLACE THIS LINE WITH YOUR FLAMES ***

To try and make a long story short, we at Tektronix, Clark County site, discovered that our postnews software was sending all of our postings to one other Tektronix computer which then dumped all of the postings to "junk". This apparently has now been fixed and so after editing out most of my postings, I reposted some of them. What I did not realize was that since my access to the other computer was a group access code, was that it would be posted as "aegroup (Dennis Ward)" and not "wrd (Bill Dippert)" -- I know that was dumb but doesn't everyone deserve at least one mistake a year? At any rate, there are many postings out in both net.micro.atari and other places, that end up with my --Bill-- signature which look like Dennis sent them and for which I apologize.

Messages may be sent to me at:
tektronix!tekigm2!wrd

Since this misdirections of messages has been going on for a least 6 months, there may be other repostings by other individuals in similar fashions. be patient with us at Tek, please!

The advantages of Action! over other languages are many. In its basic syntax
it is like a combination of c and pascal. The fact that the entire language
resides in a 16k bank switched cart(thereby looking like 8k to the computer)
gives a programmer more memory. The best feature is definitely its speed.
Action! is taylored for the 6502 enviroment and it shows. The one pass com-
piler is extremely fast and the resultant code is compact and fast.
Homepack is programmed in Action and when they ported it over to the Commodore,
they also programmed that in Action to, though I don't remember exactly what
they did. I once tried implementing an 80 column emulator in Action and was
quite impressed with the results though I realized machine language was the
only way to go for something like that that uses lots of processor time.
I also decided that any big programming tasks I ever would do in the future
would either be written in Action or machine language.

                        Scott Weisman
                        !sdcsvax!sdcc7!ln63fcv

(If you see any opinions in here, they are probably mine; if they aren't, then
I didn't write them. That means one of two things, nobody wrote them or
Lectroids from planet Ten wrote them. I tend to think the latter, or none
at all.)

In article <622@tekigm.UUCP> aegroup@tekigm.UUCP (Dennis Ward) writes:
>Similarly if either Commodore or Atari come out with 32 bit machines, then new
>subgroups could be established. ST and Amiga are too specific names, a more
>general generic name should be established so that if Atari or Commodore come
>out with new 16 bit machines with different names, the catagories would still
>be appropriate.

No, I totally disagree. You obviously have not seen the size of
net.micro.amiga or net.micro.atari. It seems to me that if anything
we *really* need to split the atari group, in the same manner as
the split of the Commodore group.

We need to have net.micro.atari for all pre-ST machines.
Then, have a net.micro.520st or net.micro.st for the ST.

Please, Mr. Spafford, if you read this, consider it a plea well-done.

Aloha,
Jonathan Spangler

Yeh, you... (rolls up sleeves and spits on hands) wanna step outside & make somethin' of it?

> Sorry, but it's not just the fact that the system uses
> windows - it's also the way they're used. There are over 400 (aren't there?)
> toolbox routines that do all that stuff for you, so your code ends up looking

> in.

Ahh, then why not isolate the Mac-specific stuff in a seperate module.

> Ahh, you say, then why not isolate the parts that are mac-specific and
> provide a high level interface that mimics the mac?

What are you, a telepath?

No, that's not quite what I say. I say write the Macintosh software with the intention of porting it to other machines. You may lose some efficiency, but you'll gain at least one huge new market for your stuff. Maybe two.

Pseudo-code. Let's use the UNIX model.

```
main {
     signal(CLOSE_WINDOW_BUTTON, close_routine);
     signal(RESIZE_WINDOW_BUTTON, repaint_window_routine);
     signal(...other_stuff..., ...other_routines...);

     main_loop {
          do_some_stuff...
#if !defined(MULTITASKING) && !defined(MOUSE_INTERRUPTS)
          poll_mouse(); /* this will call all the other signals */
#endif
          some_more_stuff...
     }
}
```

If the program is written in a manner that supports porting, then porting will be easy. This will require a certain amount of LCD coding (on 4.2UNIX, frex, CLOSE_WINDOW_BUTTON is INTERRUPT, and RESIZE_WINDOW_BUTTON is TSTOP), but the gain is portable code.

Has anyone found a way to guarantee 40 columns of text no matter which monitor happens to be in use when the program is started? Also, has anyone managed to find a way to write text with other than white (or its inverse) as the color?

Thanks in advance,
Ed Friedman

Before I invest in a 520St or Amiga, I
need to know if you can define your own character sets and how fast do the
corresponding characters appear on the screen.
Do you have to load in the entire frame
from disk to keep text screens
composed of smaller or larger than normal characters?
In essence, is their a display list mechanism or do you have to create those
larger
characters?

 ----

I don't think any of these things happened.. None of these items
ever made it to the market; the 1450 series never
made it to production, and the CP/M module was dropped while still on
the drawing boards because 1) Atari determined that the market was small
and 2) the ATR8000 and one other CP/M attachment were already out (I got
this info from Atari long long ago..) Re. the 1600XL, I've actually
only heard one other reference to it before (on SIG-ATARI); it was
slated to follow the 1400's but I don't think it got past the idea
stage either. The 1090XL expansion box was one of
the attachments lined up for the XL series, but apparently died along
with the 1400 and 1450 when Atari (Inc.) finally went down the tubes.

All in all, it seems like it may have been a good thing after all...
The old Atari was trying to fire up a new product line that was not
significantly different from the old machines, and were based on
processors that were all but obsolete, and certainly would have been
by now, even if they weren't in late 83, considering that the Mac came
out in early '84. (No flames please; I still use my 1200XL and I'm
not questioning the continued utility of the 8 bitters, only the
currency of their designs).

I guess the key question here is "what Pascal, or C ?". When Action came
out, the only C widely available was Deep Blue C, which was hardly
complete, and Atari Pascal was a horror requiring 2 drives and lots of
patience.. Action! was like a breath of fresh air, especially because
of the incredible *environment* it provided: a halfway decent editor,
monitor, compiler, all in one 16K cartridge that was only 8K on an XL
machine; not bad at all, in spite of the rather weird bugs that
cropped up now and then. And above all, *SPEED*, man, (read person if
so inclined), that baby could cruise.... the edit-compile-run cycle is
one of the best I've seen, a comparison with Basic would be like
P-system and Turbo for the (forgiveness, O Holy Ones) PC. So,
give a nice, weird product its due, one that gave me infinite joy when my
buddy's PC was beaten by a lowly 1200XL.

 (nostalgia.. guess I'll go brush the dust off 'Cyborg' tonight)

Spaces are ignored in ACTION! except as separators. I don't remember the article, but sometimes these programs are scrunched to fit the magazine's column width.

ACTION! is a compiled language designed for the Atari. It is much faster than BASIC and probably faster than about any language other than assembler. It also comes with a screen editor.

ACTION! has been out for a few years. Anyone who is a regular reader of either ANTIC or ANALOG has heard of it. One of them ran a short tutorial series on it a while back. I just wish there were more ACTION! programs in the magazines.

First---I'm tired of reading about history of abbreviations like PeeCee.
      Instead, let's think about what that could say in our days&nights,
      okay? C'mon let's have a little fun with this two letters.
      What about ProvoCation, Power Case, or Proud Computing, heh?
      Just think of the ST family and let your inspiration flow.
Second--Some damn fool used part of my hardcopy collection for his
      fireworks (winter came early this year), and so I lost a really
      important paper:
      It's been a posting on info-atari about a 4Meg-upgrade (!!!) for
      the 520ST. Could anybody send it to me once again, I really
      would appreciate that. *** thanksinadvance
Third---Once again I'm tryin' to leave INFO-ATARI. A helpful German
      gave me the advice to make a deal:
      KRAUTROCK-Video for the former moderator and he will kickmeoff.
      Okay folks, doitt.

                              so long *** wodi

<eat>

   The following information was given to me by the former chairman of the local user group's languages SIG:

   In order to run an program written in Action!, you have to either have the Action! cartridge plugged in, or you have to have purchased special software (another $99?) to tweak it into stand-alone executable mode, i.e. in order for anyone else to run your Action! programs.

  Since I don't have first-hand information on this, and haven't seen anything about it in any other follow-ups, could somebody with an Action! package confirm or deny this?

>program, mind you...

Yes, but it doesn't come naturally (nor free). You may indeed be overestimating the "professionalism" of Macintosh C programmers (though it's slowly improving, now, with examples like SKEL available and all the books out). From what I've seen, many of them had never written in C before they got their Mac. Also, someone on a 128k Mac doesn't have the spare memory to add all the #ifdef's to their code in the first place.

>[porting software to radically different environments]

An example of portable software for various windowing systems is "Brown Windows", which runs on Suns, Apollos and other workstations. But this is a LARGE shell of extra software, and after porting it to the Mac I believe you would be left with little space for your program, AND the user interface wouldn't be too Mac-ish. The same would be true for GKS.

The best approximation of what you want would probably be using the Aztec "shell" environment and go back to printf. Then you can write portable programs that run with no modification on Unix and Macs. But: no windows, no mouse, no dialogs, not a single Macintosh-like feature (even the corners of the screen aren't round any more!). Here it would even make sense to port curses :->

Yes, BUT WHERE WAS COMMODORE-AMIGA????

Why did Commodore pull out of the show at the last minute? They were in the
exhibits guide (stand M1032 at the MGM Hotel), but the space was occupied by
other exhibitors.

Atari, on the other hand, was VERY present, showing many colour applications
for the 520ST, and (cheeky) had an Amiga, a Mac, and a 520 side by side, all
running versions of the (in)famous "Bouncing Ball Demo". Undoubtably, the
520 LOOKED best, and was running at the same speed as the Amiga, however no
sound being demo'ed from any of them, and the Amiga was the only one which
had the horizontal portion of the background grid displayed. I have a feeling
that this might have been ommitted on the 520 version for a (? performance)
reason. Good marketing anyhow, as was the separate stand paid for by Atari
but full of small independant software developers for the 520.

Is Commodore in so much trouble that they cannot afford to market their

products at one of the most important computer showcases??

I am looking for a working Atari 400 keyboard. My kids would like to play
some of the games that we have but some of the keys on the good 'ol 400
membrane keyboard are either non-functional or stuck closed. If someone
has a keyboard that they are willing to part with (or knows where to get
a CHEAP substitute), please contact me.

It appears that LINE INPUT from a file in ST Basic ignores the first byte of a file. On my system, this program types out all the input file except for its first character, and bombs on an end of file error at the end of the file.

```
10 OPEN "I",1,"INPUT.FIL"
20 WHILE NOT EOF(1)
30 LINE INPUT #1,X$
40 PRINT X$
50 WEND
60 CLOSE 1
70 END
```

In the model 400/800 machines (and probably in the XL's), you can modify the display list to form custom screens. You can actually see the changes being made by POKEing new values into the current display list. All except for the very last display list instruction which is a JUMP to a two byte address which is the beginning of the display list. (This way you keep looping thru the same display list over and over to keep the screen refreshed).

My question is why doesn't changing the last instruction or address have any effect? I've even POKEd zeroes into the last three bytes of a

display list and seen no change to the screen.

Here is a version of uuencode that will run on the ST when compiled with the DRI-C compiler.

This version was hacked out of the uuencode.c that appeared on net.sources a while ago. Uudecode.c, if I remember correctly, worked right away so I did not bother to archive it. You should be able to get it off net.sources.

The only portion that had to be modified was the part of the code used to open a file. The original file used efopen() which then called fopen(). I had to modify it to fopenb() to open binary files.

The source follows. Link it with osbind.

Enjoy.

```
/*
 *
 * Uuencode -- encode a file so that it's printable ascii, short lines
 *
 * Slightly modified from a version posted to net.sources a while back,
 * and suitable for compilation on the IBM PC
 *
 */

/*
 * Modified for the Atari 520ST  (October 27, 1985)
 */

#include <stdio.h>
#include <osbind.h>
```

```
char *progname = "UUENCODE";

#define USAGE "Usage: UUENCODE file [>outfile]\n"

/* ENC is the basic 1 character encoding function to make a char printing */
#define ENC(c) (((c) & 077) + ' ')

main(argc, argv)
     int argc; char *argv[];
     {
     FILE *in, *out, *efopen(), *efopenb();

     if (argc < 2) {
          fprintf(stderr, USAGE);
          exit(2);

I've seen AtariWriter + at B&c ComputerVisions and San Jose Computers.
It retails for $49.95 and comes in a white manila-like white envelope
with black bold letters.

                        Will Hom

Hi, you've probably already got a dozen answers on this one, but since I know
the answer I thought I'd throw in my two cents worth.
   The Atari OS stores the location of the display list in locations 560, 561
(decimal usual low, high format). Every 60th of a second a vertical blank
interupt is generated and this 'shadow' value is put into 54274, 54275 which
tells the hardware to really find the display list. So, in effect, it makes
the last instruction almost useless, the only thing it does is tell the hardware
to stop sending stuff to the screen. In other words if you want to change
whereyour display list is located you'll have to chage the 'shadow' memory.
If you want to know ALL about the Atari 800 and related computers your best
bet is the book "De Re Atari" it's just packed with useful info.
Well I hope this answered you question. Have fun.

I am a new subscriber to this newsgroup, and am very interested in the
references to upgrading an 800XL to more than 64K in a fashion compatible
with the 130. (I have heard disturbing rumours that new Infocom games will
not run on the 64K 800XL, and that's what I bought my machine for).
Could somebody please send me (johnf@apollo.uucp) the reference to the
original article, and any comments they feel are appropriate? Thank you.

P.S.   Byte Magazine Folding ?   My copies ALL fold down the middle :-).

Ken,
Because OMNIVIEW is in gr.8 it does use up about 6K more memory than a 40
column gr.0 screen. With Letter Perfect this means a 21K buffer instead
of 28K. The bit-3 board on the other hand has its own screen memory and does
not require any of the 6502's. In fact, some developers have put this
feature to good use by using the bit-3 output for debugger output while
simultaneously displaying graphics on the ATARI output.

I too have noticed that zeroing out the last 3 byte jump instruction of
the gr.0 display list seems to have no effect. The only thing that I can
figure is that ANTIC must be sometimes smart enough to know when it has
reached the bottom of the screen and simply goes back to the beginning
of the list. This is not always the case however because you can make the
screen roll if you put too many instructions in the list.

I have not seen Atariwriter + yet but I have talked to people who have
used it. They say it does not compare favorably with Paperclip, which people

generally rave about. One redeeming feature, however, appears to be the
spelling checker which will work with any DOS compatible text file.
AT least this is what people tell me. To me this is all moot anyway
since I am an 80 column snob.

Bill,
I developed and market OMNIVIEW. It will not work with the 1200 because
the 1200 has a different chip set for the OS, which the last time I
took the time to investigate would make the price of that version
prohibitively expensive. OMNIVIEW does look great on a monitor with
separated video, which includes the Commodore 1702 and even better the
Technika (sp?). I know of no way to get RGB out of the 8 bitters and if
anyone knows a way I would appreciate hearing from them.

Bill,
As I stated in a previous message, we do sell a 256K upgrade for the 800XL
and 1200XL that does make them look like a 130XE for $99.95 ($49.95 w/o
RAM). Send me your address and I will send you some lit.

In response to everyone looking for or asking about HCI's Happy Revision 7.0 for the Atari 810 disk drives.

I talked to Richard Adams last Thursday (11/21/85) and he has assured me that the new revision will be shipped BEFORE the end of this year. Like many others, HCI has had my money for Rev. 7.0 since last January, but unlike anyone else, HCI also has software that belongs to me. They have had this software for over 1.5 years. I have been told (again by Richard) that only a few changes are left to be made to the software, before it can be shipped.

As soon as I get the new revision I will post the fact. And if anyone else gets it, PLEASE post the fact here, or send me mail. I really miss my software. I hardly remember what it is, or what it does.

> -------

Again, I have to ask a question previously asked by another: who is "we"?
I have never heard of CDY Consulting -- although from your name and the
initials I presume it is you company? Are your products available at
computer stores or mail order or? (By the way, I actually posted this
message, not Dennis, this is part of our reposting screwup here at Tektronix
Clark County site.) I am sure others would be interested in learning where
these "products" are available. I realize that you cannot advertise over
the net, but can you at least answer specific questions like this?

Also, is this upgrade compatible with the 130XE? There was a previous posting
by someone to the effect that some changes had to be made to I believe DOS 2.5
to get it to recognize the additional memory and to allow for both D8: and D7:
RAM disks.

Thanks in advance,
--Bill-- (not Dennis)

According to our local dealer, there is an ST developer's kit available for
$300 from Atari. However, he didn't seem to have a very good idea of exactly
what the kit includes -- I gather it comes with a C compiler and some other
random utilities. Can anyone out there in netland provide more details? Is
there a good reason why one should spend $300 on the developers kit versus
$65 for Hippo C? (Better compiler, better text editor, etc?)

Summary: please send me votes re Atari groups

I raised the suggestion of splitting atari into 800 and ST groups
a while back within the atari group, only I never counted votes.
Here is my proposal, please send me mail and I'll post the results

Is a deadline of 12/1 fair?

> Resolved that net.micro.atari be replaced with net.micro.atari800 and net.micro.st (because atarist sounds like a real word). The old group should go away or no one will notice the new groups.

No flames please, just votes. Certainly no sarcasm since sometimes I am dense and may count your vote wrong. So either say "no", or "yes", or "yes but with different names." If there are more suggestions for different names than just plain yeses I'll post all the possible names and we'll vote again.

I have seen that there are a number of C compilers out there for the ST. Has anyone had enough experience with any of them to give a thorough evaluation? Also, I would like to know if any of them have options for producing PROMable code. It would be nice to be able to use my ST as a development system.

>

This is beginning to sound like the old "What's the best language" debate
that has raged ever since the first FORTRAN compiler in the 50's, or even
earlier with "what's the best assembly language architecture?" Unfortunately
most programming languages (C especially) allow too much flexibility in the
implementation. This is compounded by the fact that there are too many
un-obvious choices to make when adapting a language like C to the Mac. (The
old "glue routine" problem.

I has been the experience of many that no matter how well certain differences
between two architectures are understood, the job of porting from one to
another is non-trivial. IFDEF's are currently the best solution to this
problem, but they must be applied manually, and as the program becomes more
complex, the IFDEF's make it harder and harder to read.

The Mac has made portability even harder by stressing the concept of user
interface consistency. Most Mac users agree that it is the Mac's unique user
interface, and Apple's ability to convince third party developers to abide
by that interface is what sets it apart from most other machines. The Amiga
and the ST also have a window oriented interface, but they do not have a
company behind them like Apple that stresses user interface consistency.
In the case of the ST, the system disk contains examples of programs that

violate the user interface (The terminal DA, View File) and the Amiga has too many features which simply make it inconvenient at times not to use the standard interface.

"Portable" Mac programs, thus, simply are not looked upon as highly by Mac users unless a significant amount of work is done to make them "Macish" at which time they are no longer portable. The Amiga, with 256K of ROM and all sorts of fancy hardware also inhibits portability. The ST eems to be a parasite that cannot live on its own, so it must stress portability (with IBM PS's running GEM) else clutch at what ever straws it has for a market other than its price.

Most computer manufacturers (especially those making IBM clones and UNIX boxes) stress portability in order to decrease the amount of work that they have to do to be accepted into the marketplace.

Other companies, Apple, and Commodore/Amiga, being two striking examples, have decided that their products are unique enough so that portability is no longer an issue and third party developers are willing to create software that will only run on these machines. It is obvious that Apple has succeeded in this regard. Commodore, having a much newer product, hand having current financial difficulties has yet to prove that the Amiga can survive, but at least they are trying.

Users of these machines are not only interested in using software that works, but also software that makes best use of the unique capabilities of their machine. (Otherwise, they would have bought a machine which runs "portable" software.)

It is thus simply not practical to post one source and expect it to fully take advantage of many different architectures.

One of the worst problems in thie regard that is plaguing the Macintosh is the lack of many programming language environments which have been designed to specifically support the Mac architecture. Most, if not all existing systems were ported from other machines and thus bring with them constructs that simplyt don't work on the Mac. The most common of these is the TTY window. This is a concept that has been part of most languages since the very first machines. (The EDVAC, one of the earliest Von Neuman machines used a Baudot teletype and paper tape for I/O) Unfortunately, with very few exceptions, language developers have deemed it their duty to support all of the standard features of a language even if those features run contrary to standard Mac programming practice. A perfect example is a PASCAL ReadLn, or a C Scanf. Both of these routines block until a CR is received on the input stream (i.e. the user tytpes RETURN). This is NEVER done in a good Macintosh program because it disallows other activities that the user might want to do such as work with another window, open a Desk Accessory, etc.

SO WHY BOTHER SUPPORTING PORTABLE LANGUAGES????

Some people might argue that readln and writeln are useful on the Mac for

debugging. A much better way to debug is to use a symbolic debugger. Why havn't developers been writing good symbolic debuggers rather than spending lots of time and effort supporting features that are not conducive to good Mac programming?

I have been using ACTION! for large programming projects for two years now and find it to be far and away the best development environment for the Atari 8-bit computers. ACTION! is a block structured langauge similar to Pascal and C. My best guess as to why Clint Parker (the creator of ACTION!) decided to invent a new language instead of using Pascal and C is that he had his own ideas about what a programming environment on an Atari computer should be like and he didn't want to compromise them for the sake of limited compatability. After all, the idea was to unleash the power of the Atari (e.g. allow assembly language control in a high level environment). This could hardly be done by porting C programs from another environment. The advantage of ACTION! over BASIC could hardly be enumerated in a short message. The primary advantages are: run time speed, structured syntax, accessability to advanced Atari features (DLI's, P/M graphics, etc.).

The indentation in an ACTION! program is used purely for readability of the source code. The particular spacing for any given program is based solely on the desires of the programmer that wrote it.

John Felton

I have no connection with ACTION! or O.S.S. except as a happy customer.

that's strange. Let us all know if you get an answer. You would think
that it would be nice to jump between alternate or multiple display
lists, as one possible implementation of animation, etc. It sounds like
the hardware responds to a JMP instruction by using the start address
pointed to by that pointer in page mumble where the start address of the
display list is stored, ignoring the one provided by the JMP
instruction. I can't believe that is really the case...

     Dan

----- End of forwarded messages

Dan,
     Yes, animation and multiple screens (like a double exposed photograph)
are exactly what I had in mind when I found out the display list jump address
was being ignored. Your explanation seems to be exactly what's happening.
     My thanks to others who responded (I won't repeat their messages since

copies were cc'd to the net).

I understand through people who went to COMDEX in Las Vegas
that Commordore didn't even show up with the Amiga.

Seems a bit odd considering the money put into their advertising scheme...

Instead, people at COMDEX saw an absolutely fantastic display
of the same bouncing ball demo running -- SIDE-BY-SIDE, mind you -- three
machines: 520ST, Amiga, and Mac. All three were running the same ball demo.
Because of the speed difference, the ST was the clear winner, but not only
becaue of the speed, but also the color which was much more brilliant.

What do you think about this? Why didn't Commordore take the Amiga to
Comdex? Why am I not reading anything about it in December PC magazines?
How is the $124 million loss for 3rd quarter going to affect them?

Please direct answers to the net as I'm sure all are interested.

Puzzled, but with aloha,

> be appropriate.

I disagree with the above. If we start breaking everything up into groups
based on certain aspects of the subject we would have:

net.jokes.clean
net.jokes.offensive
net.jokes.bad
net.jokes.notunderstandable

net.jokes.notreallyajoke

I think you get the picture! I like having the .cbm and .atari groups the way they are because I can post articles that may reflect all commodores and not have to post the article in many places.

Any comments may be sent to /dev/null ....

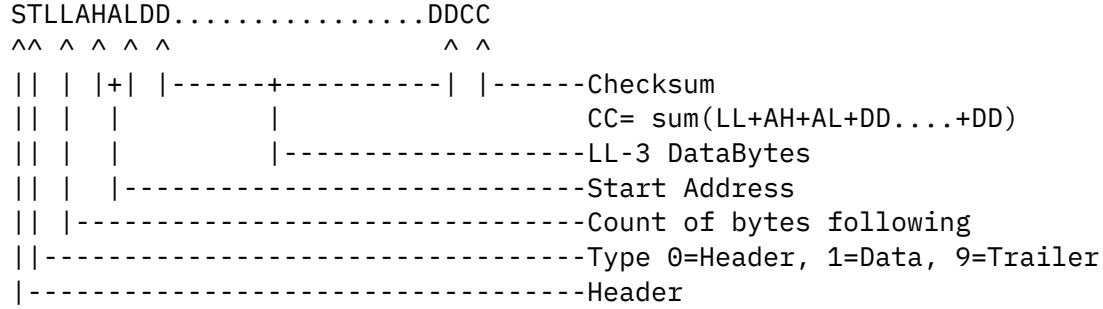
     For the sake of some kind of standardization, may I suggest Motorola

S record Hexfiles? At least if you use this format you will have some
chance of making use of routines generated on other 68000 systems. The
spec can be obtained from Motorola, but here's the overall scheme:



(based on art of David L. Kindred)

Cheers! -- Jim O.

This is an obvious use of subgroups. The 520st group should be called
net.micro.atari.520st. net.micro.amiga probably should have been
net.micro.cbm.amiga, and net.micro.mac should be net.micro.apple.mac.

Right, either you need the cartridge, or the software must have been compiled
with the runtime package. However, the price of the run time package wasn't

$99.00. Actually, you don't need the runtime package to run software compiled with the runtime package, there is lots of PD software written in action and compiled for use by the general public. There is also some commercial stuff, such as Homepac, developed using action. It is the best 6502 development environment around, and is well worth the investment.

1 C compiler, assembler, linker, all of decent quality;

1 text editor, sort of like EMACS, 4 out of 10 in quality;

Assorted CPM utilities, and a program to exit gem into TOS (CPM);

A Batch program to run CPM commands from gem;

A ton of documentation varying from fair to awful, all of it essential and

unavailable elsewhere;

One gem application, the RSCS (resource construction set,) apparantly useful for building other gem applications, very poorly documented and of dubious quality, but interesting as a sample gem application.

Reports on Hippo C are extremely dubious.

I was recently given an Atari Trackball as a present. Unfortunately, it was purchased several months ago, making it well "out-of-warranty."

Problem: It won't send the bits that indicate left-right movement.
         I get up-down and fire, but no left-right.

I opened it up and there are 5 chips inside -- a couple logic and a multivibrator. Anybody have the schematics or know where to get them?

Thanks.

>proliferation of languages anyway? I'm still trying to learn AB,MBII and
>BXE/BXL, familiarizing myself with C, let along trying to learn Pascal and
>Action!
>(Flame off)

Action! is a compact, powerful, structured language. It can easily be
used to write sophisticated code taking advantage of specialized system
hardware. It compiles quickly, and can be used to generate stand-alone
applications.

Action! is available as a cartridge from O.S.S. The cartridge takes up
8K of user memory, but contains (I think) 24K worth of code inside.
It consists of three different programs

     (1) a full screen editor.

(2) a compiler
(3) a run-time support package

In addition, O.S.S. offers a stand-alone run-time package (both for commercial and private release), and a toolkit of useful packages. It is possible to write very complicated programs in ACTION!. I have written both an 80 column software card in ACTION! as well as a number of graphics games.

In action it is possible to write dli, vbi, and interrupts attached to other system timers. There are a number of bugs in the cartridge, but they have been quite well documented in Analog magazine.

To give you an idea of the flavour and power of the machine, I have enclosed a very simple game (the idea of which was stolen from an Analog game which was published in 6502 code). You are a rabbit, and your job is to pick up numbers that appear on the screen. In addition, you have a gun which can be used to shoot the numbers (you don't get any points for them), and to shoot at the walls which will close in on you. You will need a joystick in port #1 to play the game.

About ACTION!. Spacing is up to you, the compiler doesn't care.
There are a number of tricks in the following code. The first CARD array is allocated memory last, so the address of "last" will contain the first usable memory location. This game builds its own screen and allocates space for the display list, players, etc. Declarations of the form
CARD x=$FFFF
declare x as a CARD (16 bit unsigned) allocated at memory location $FFFF, while
CARD x=[$FFFF]
declares x as a CARD with initial value $FFFF. Note that routines can be coded the same way (see SETVBV for example).
All declarations are static, and subroutines are not recursive. Code blocks can be included (SAVETEMPS and GETTEMPS are code blocks) to allow machine code to be included in-line. SAVETEMPS and GETTEMPS save the ACTION! registers for interrupt routines.

1. keep the database of addresses to which the list is forwarded UP TO
DATE (this is the most important function).
2. provide some way for all addresses listed in the database to receive
each posted message individually, but NOT get bounced mail. (Suggestions for
doing this were posted to the list about a month ago; they are in the
archives.) (this is the second most important function).
3. have a lot of disk space to hold the archives, which includes every
message posted, and a moderate amount of software donated to the list.
4. have the archives in a location where EVERYONE on the Arpanet, and
possibly everyone on the usenet, can list the directories and ftp the
files.
5. respond to requests for archive files to be mailed to users without
ftp access.
6. take submissions from users and put them in the archives, provided
they are offered WITH NO STRINGS ATTACHED (i.e. they must be in the
public domain).
7.
(note:the archives are now located on su-score.arpa in directory
ps:<mrc.atari>*.* . The database is on su-score.arpa in file
ps:<g.tang>atari.dis . New moderators will also want to see the
atari-related lines in <mail>mailing-lists.txt on score.)

The ST software development kit includes:

SOFTWARE
     Digital Research C compiler, 68K assembler, debugger, linker (two
     different ones), Kermit, GEM tools, examples etc....

DOCUMENTATION
     Disclaimer, Non-Disclosure agreement, Introduction to GEM Programming,
     GEM Setup Guide (IBM example only), GEM AES Programmer's Guide Vol. 2,
     GEM VDI Programmer's Guide Vol. 1, GEMDOS Specifications rev. 13,
     Example GEM Program Listing, DRI "C" Programmer's Guide,
     DRI Assembler & linker manuals,
     ST BIOS listing (reference only),
     ST Hardware specifications, Printer specifications,
     Kermit User's Guide, Intelligent Keyboard Specs,
     ST schematic, ST to IBM Keyboard Translation Suggestions,
     Line-A (graphics primitives) documentation,
     Sound chip documentation

The C compiler isn't too hot -- but it works.

One of the better development setups for the ST is two floppies and a 1mb
machine with a 512K ramdisk. A hard disk is, of course, even better.

If you have questions about the development system, call Richard Frick
at (408) 745-4922.

(I must be an old tim'r...) Back in '84 someone had proposed and implemented a means with which to send and receive non-ASCII files through the net. The system consisted of two programs BINHEX and HEXBIN (remember now??). They are Atari BASIC programs that translate an Atari file to ASCII form hexadecimal ("printable hexadecimal") and back to an Atari file. The procedure worked as follows:

sender:
Runs BINHEX program on Atari, converting the Binary file to printable ASCII format.
Transfers ASCII format file to net host via Kermit, XMODEM, or whatever. . .
Sends ASCII file to info-atari via host mailer.

receiver:
Reads mail on net host.
Sends mail to file on host.
Edits out Mail header/trailer garbage to retain only ASCII hex and BINHEX checksum info.
Transfers file from host to Atari computer.
only the ASCII Hex program/file representation.
Runs HEXBIN on that file to form original binary file.

After the initial release of the BINHEX, HEXBIN programs, one or two minor bug fixes were posted. I will transfer my fixed versions (If I can find them) or the original versions of the progs (which I have on my Arpa host, luckily...) to this mail-group shortly.

Now that I think about it...Those progs might still be on the Atari file repository, wherever that is now. Was SIMTEL-20 at one time.?

About a month ago, I requested information concerning the "Quarter-Meg Atari 800XL" article appearing in BYTE 9/85. At the time, I had just ordered the necessary parts and was awaiting delivery. I have since received those parts and have performed the upgrade.

The hardware apparently works well, however, the RAMdisk software from BYTEnet has problems. I have not been able to get it to work. My DOS2.0s has been configured to recognized Drive #3. The ATARIRA2 .ASM file (from BYTEnet) has options Drive 3 single density defined. The source code was assembled to produce an AUTORUN.SYS. Upon booting, I get a momentary screen flash of garbage resembling multiple "=" signs across the entire screen when the AUTORUN boots. This does not seem to be a problem. Once the DOS menu appears, the RAMdisk (D3:) should be formatted. This operation causes the machine to hang.

Upon further investigation it appears that the "format" process operates on banks 5 thru 0, respectively. In the source code, the initialization code to set-up a given bank is accomplished in routine SETBNK, while the format code is in routine FORMAT. FORMAT controls the procedure calling SETBNK via a JSR. It appears that bank 5 formats properly, switches to bank 4, then hangs on the RTS return from SETBNK to FORMAT. In fact, all *odd* banks format properly while *even* banks blow-up. Apparently the return address for the returning RTS has been damaged in the stack when *even* numbered banks are swapped in.

Since I am not an 6502 assembly language wizard, I do not have a FIX. I am depending (hopefully) on one of you guys to correct this situation and release it to the World.

Judging from the responses I've seen on the Net, a number of us are having similiar problems/interests. Since a 256KXL is of particular interest and has exciting possibilities, I suggest that those individuals interested form a Users Group of our own. I will be willing to act as a clearinghouse for information. It is to our mutual interests to share whatever associated information/software that we can obtain. My address is

>
>Further news: they haven't yet made a 256K 1200XL, but they've opened one
>up and said it can be done.....(etc.)
>
> - joel "vo" plutchak
>   [allegra,ihnp4,seismo]!uwvax!uwmacc!oyster

Thank you, Joel, we appreciate the help. In fact, about 3 weeks ago my
AUG, Potomac Atari Computer Users (PACU), president Fred Ward wrote to MAAUG
requesting the information. To date, there has been no response. We would
appreciate it if you could query your folks as to the issue. I'm supposed
to demo this thing at the AUG meeting this Saturday!! Further, your
suggestion of sharing info between user groups is good. Our group would
be glad to pass any information you could provide to other groups in
the Washington Metropolitan area (or anywhere).

In article <djk611@uiucuxa.CSO.UIUC.EDU writes:

>yes the mod works... be careful when assembling the code

Please enlighten us!!! Given recent Net articles and what has been
written above, what is it that you did that allows the mod to work?
Are we talking the same "mod"? Did you do anything special? Was the
upgrade completely successful for you?   We would appreciate your
insight.

In article <DYOUNG@USC-ISID.ARPA (C. David Young) writes:

>We have been shipping the 256KXL for a couple of weeks and no problems
>have been noted. It makes the 800XL look exactly like a 130XE except that
>bits 5 and 6 of $D301 have been redefined to address twice as much memory.

Who are "we"? Can you please explain the theory of the bit-usage of
PORTB ($D301) and the significance of its use. Also, how can a given
bank be directed to the upper or lower 32K when swapped in?

In article <scp@akgua.UUCP (S.C. Pierson [Stephen]) writes:

>I've currently upgraded a 1200XL to 256K using the article from the
>september issue of Byte.....When we run Ramsgl or RAMdbl and format a
>drive, the screen turns to blue and white horizontal stripes from top
>to bottom. The rest of the computer works fine, it's just when we try to
>access the extra ram for ramdisk that it seems to fail and lock-up.....
>   Steve Pierson
>   AT&T Network Systems Atlanta Ga.
>   404-447-2142 c 583-2142

Steve,
This is exactly what happens on my 800XL. My stripes come at boot-time
for only a second, while the machine just hangs when trying to format.
Whatever info. I get I'll try to pass along.

In article <DYOUNG@USC-ISID.ARPA (C. David Young) writes:

>...I just finished souping up the ramdisk handlers in OMNIVIEW XL/XE
>to treat the extra RAM in our 256K upgrade for the 800XL....

Also, in a following article C David Young writes:

>That 256K RAM upgrade in BYTE was a real dog. We have got a 256K upgrade
>(256KXL) that will make your 1200 130 compatible. You can buy it without
>RAM for $50 or with for $100.   The reason that the BYTE upgrade is such a
>dog is that it ends up including the stack in the bank switch area.

Hurray for Dave!!!!! Can we purchase just the software you've created for
this upgrade? If so, where can we order? Or, can you pass along the
patches necessary to kick-start the BYTE "dog" that us suckers have
fallen for. It is wonderful to know that we are not without
alternatives in this situation.

In article <dsaker@iuvax.UUCP (Daryel Akerlind)

>I too want a copy of the answers. thanks

and artivle <BillHolland.ES@XEROX.ARPA

>Please copy me in all answers, Thanks

Consider yourselves copied. We would appreciate any experiences you've
had in this matter, thank you.

Anyway, this has been long enough. I'm preparing a letter to
Claus Buchholz author of "The Quarter-Meg Atari 800XL". Any replies
I'll post on the net. I would appreciate any other contacts/replies.

Summary: Magazines worth Buying

In article <7500005@uicsl> hr@uicsl.UUCP writes:
>RE: folding
>
>   ".. Creative Computing is soon to print its last issue.."
>Z.D. has pulled THREE magazines from under me in about as many years.
>(Then FNE went commercial and pulled "DTACK Grounded".)

(The above has been a bit edited)

     While there are a number of Atari Magazines available, may
I suggest that those interested in 68000 technology also look into
(and hopefully buy) 68 Micro Journal. It's main thrust is single
board computers, and *all* Motorola chipsets. It has supported the
Radio Shack Color Computer well in the past and I expect it would
support the Atari as well, if Atari users supported it. There is
a very important roll that this magazine has played for the Color
Computer and can play for the 520ST users. They are *not* biased
and call a spade a spade. They have been openly critical when deserved.
The value of that as opposed to the rose-color glasses approach of
most magazines is refreshing. The extremely high quality writing

is also. How many other magazines have been able to boast a long running series on Ada (5 parts so far)? Few magazines have printed as much on the 'C' language. Flex, Uniflex and OS-9 are supported in 6809 and 68000 family forms. I hope you support the various dedicated Atari magazines as well, but don't overlook the wider picture.

Cheers! -- Jim O.

Yes, Haba has a disk full of utilities which do exactly that.
    A friend of mine who used the Norton Utilities is VERY satisfied
with the Haba utilities. It costs about 35 dollars.

I have seen software driven 80-column packages for the ATARI, but they do this by drawing the characters on a graphics 8 screen, which uses up mucho memory. Is this a problem with the commercial hardware products (omniview, bit-3)? How do they work?

Does anyone know:

     where Teknika monitors are sold?

     retail stores where they may be viewed?
     (hopefully locally, but anywhere is fine)

     how compatible is the MJ22 with Atari, Apple and IBM?
     (for computer upgrading without new monitor requirement)

     information on servicebility and/or reliability of them?

Thanks in advance, --Bill--

Has anyone out there been able to successfully use the computerized traffic generator program written by Bob Fink in the Februrary 1984 issue of Model Railroader magazine? Either as written in Microsoft BASIC for the TRS80 Model I computer, or translated into Microsoft BASIC for Apple, Microsoft BASIC II for Atari, etc.? I am trying to translate it from the original to Atari Microsoft BASIC, and am not having much success. I question whether the program as written in MR will even run on a Radio Shack TRS80. I have found what appear to me to be several fatal programming flaws. I would appreciate any help from any other model railroaders working on this. Thanks in advance.

Xref: watmath net.news.group:4648 net.news.adm:434 net.micro.atari:1708
net.micro.cbm:1830 net.micro.amiga:804

Several new groups are needed and several old groups should be renamed:

net.micro.cbm   should be net.micro.cbm8 for Commodore 8 bit machines
net.micro.amiga should be net.micro.cbm16 for Commodore 16 bit machines
net.micro.atari should be split into
                net.micro.atari8 for Atari 8 bit machines
                net.micro.atari16 for Atari 16 bit machines

Similarly if either Commodore or Atari come out with 32 bit machines, then new
subgroups could be established. ST and Amiga are too specific names, a more
general generic name should be established so that if Atari or Commodore come
out with new 16 bit machines with different names, the catagories would still
be appropriate.

Owning both an 800XL and a 1200XL, I don't see what your problem is. I have used both with my Legend 1380 printer without any problems. (I prefer the 1200XL to the 800XL any day due to the differences in keyboard feel.) For the printer interface, I use the Axiom AT-(I forget the model number--but there is only one Axiom interface made for an Atari) and it works fine. Maybe the secret is that the Axiom AT(xx) supplies its own power thru a stepdown transformer. (It is designed to also work without the power supply it says, but I have always used the separate power supply.) I have found the Legend 1380 printer to be an excellent Epson clone, at an approx. 25% lesser price. It is totally Epson FX80 compatible -- however, it does not have NLQ as the new Epson FX85 has. Like you, I wish there was a way of upgrading the 1200XL to greater memory. While we're discussing memory upgrades -- is the 256K memory upgrade as shown in BYTE for 800XL, 130XE compatible? It would be nice if all of the memory upgrades were compatible so that commercial software for the 130XE would be useable. I am about to purchase a 130XE and I would like to be able to upgrade the other two machines to equivalent memory with common software. (I once owned a 600XL, the only Atari 8 bit machines that I have not owned were the original 400/800, so I am not in the least prejudiced towards Atari.) Due to all of my periperals, etc. for the XL/XE series, I have no interest in a 520ST, although it would be my machine of preference over the Amiga. (If Commodore goes bankrupt, will Tramiel buy the Amiga back?)

I would like to convert both my 800XL and my 1200XL to at least 128K so that
the programs I use on my 130XE would also work on the other two. Namely:
Atariwriter+ and Syncalc+ (130XE version) -- when these programs are available,
no I do not have them yet.

Question: does the 256K mod allow for this or does it do a different form of
bank switching/addressing? If different, would it be possible to do a 128K
only mod that would be compatible?

Also, is anyone planning to produce a circuit board/kit, etc. to make this
conversion easier? I would definitely be interested in same, assuming cost is
not to much out of line. (After all, I only paid $139 for my 130XE, why pay
more for an upgrade kit!)

Antic Magazine puts out a terminal emulator program called "Chameleon" which contains in the documentation a termcap to use with Chameleon. This allows your Atari 8 bit machine (XL and XE) to act as a terminal for interfacing with UNIX systems. This is what I use at home to get in and out of the Tek computer systems as well as the net. I am not positive whether it will work with the original 800 computer or not. It works fine with the 800XL, 1200XL and 130XE -- does not work with 600XL as it requires the use of a disk drive. [Unless you have fixed your 600XL up to somehow work with a disk drive (with 16k memory) or have added memory to it.]

~~~~~~
******Line eater, eat your heart out.
~~~~~~

Does anyone own or have seen any of the following announced Atari computers (either prototype, early production or ?) that they might be willing to discuss and/or possibly sell?

The model numbers that I am interested in more information in and possibly obtaining are:

```
         1400XL
      1450XLD
      1600XL
      CP/M Module
      1090XL Expansion Box
```

Some information has been published on both the 1400XL and the 1450XLD, catalogs, etc. and there is some evidence that both of these saw limited production. I have not been able to find out to much about the 1600XL, but speculation seems to be that it was the first prototype for the eventual 130XE put out by the current Atari Corp.   I have seen early prototype 1090XL expansion boxes that were not complete (i.e. no circuit board cards and incompete stuffing of components) with no documentation. Sear's apparently did sell some of the CP/M modules but how many? (Sear's did catalog both the 1450XLD and the CP/M module, but admitted to only ever stocking the CP/M module when I tried to order both--they said that they had never received any 1450XLD's and then later said that they were out of CP/M modules.)

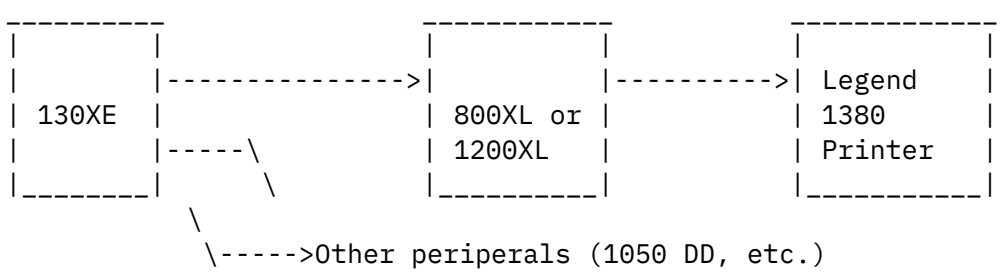
Does anyone know how to connect a spare Atari (800XL or whatever) between the primary computer and a printer? The idea being that the spare computer would act as a 64K printer/buffer. The setup that I would like is as follows:



Since the other periperals would be using the standard Atari bus, I would assume that the printer/buffer would somehow use a joystick port to joystick port or joystick port to Atari bus (at the 800XL) type cable/interface. Does anyone have any ideas on how to do this and would it require special software (such as an addition to the printer driver that I am already using for the 1380)?

Thanks in advance.

Does anyone out on the net know whether or not the 1400XL and 1450XL machines ever made it into production? I keep hearing rumors that there are both types in use by various people but my understanding was that they were prototyped only. Of course how many were prototyped is questionable. If more than 100 were built up then I would consider it limited production. If anyone has one of these in their hands please respond. Is it useable and do you wish to sell it?

In a similar note: both Antic and A.N.A.L.O.G. magazines mentioned in the past a "1600XL" machine. Was this a 128k machine and if so, was it the predecessor of the 130XE? In a similar vein, were any of the 1600XL's built and if so, are they available from anyone? If the 1600XL was a 128K machine, was it software compatible with the 130XE or did it get developed far enough to say.

I have seen the 1090XL expansion boxes. Several of the user groups obtained them from Best Electronics who were selling them locally last summer at a computer show. They were barebones, with no p/s or doc's. They did not look like they were operational. Does anyone know, did this project ever get to the stage of being saleable/operational and if so, are they available? Similarly, did the C/PM module ever get built/operational and are they available?

Atari Inc. has come up with many good ideas that some of us would like to have been able to purchase, but the products never made it to marketplace. Atari Corp. under Jack Tramiel is continuing the tradition, what with the 65XE, 130ST, etc. I wish they would do more marketing surveys and less marketing by advertising potential products. At least Atari Inc. seemed to bring most of their ideas to some form of limited production or prototyping even though they never made it to the marketplace.

Thanks in advance for any information or other.

Why don't you start with some of the questions that have been asked in just the
last week on net.micro.atari? I do not see why we need to start sending
questions to two groups, when one should do. Partly, this is probably due to
my not understanding how your example works. Could you make it a little more
clear for us neophytes?

                    Thanks,
                    --Bill--

> BASIC. Thanks in advance,
>   --Bill--

By judicious reading of the advertisements in Antic and A.N.A.L.O.G. magazines,
I was able to partially answer my own questions. Action! is a cartridge
available from O.S.S. and presumeably is another distinct computer language.
However, I am still griped that the original article did not make this clear
and I am still uncertain as to why the odd spacing of the lines. The
indentation number of spaces does not seem to follow a logical pattern. (I
thought that each succeeding indentation was another 2 spaces, but then I found
some at 4 spaces, etc.)

(Flame on)
What is the advantage of Action! over BASIC, Pascal or C? Does it fit in one
of these "families" of languages or is it a new one? Why we have such a
proliferation of languages anyway? I'm still trying to learn AB,MBII and
BXE/BXL, familiarizing myself with C, let along trying to learn Pascal and
Action!
(Flame off)

Thanks,
--Bill--

I also tried to join this mail list. The first address bounced back as unknown. So far (24 hours +-) the message sent to the second address has not bounced. (But they often don't bounce for 2 or 3 days -- I often wonder why it takes so long to get messages posted.)

Keywords: Shugart 1002,fasi,scsi,sasi
Summary: anybody done it?

(munch)

Well I bought a pair of Shugart 1002's (5 mb) and a controller card from the local surplus outlet to hook up to my cpm computer. Then I was wondering, if I got another controller card I could hook 1 up to the cpm (xerox 820-II) and 1 to the ST. Well I dug through all the old news and there doesn't seem to be enough information there to do it. Has anyone figured out how to make the (fasi?) port on the ST compatable with a normal hard disk controller? (sasi? scsi?) Has anyone succeded in attaching a hard disk to the ST?

All information will be appreciated. I have the two prior messages from this newsgroup concerning hard disk hookup.

Thanks in advance

Billj

I wrote BINHEX and HEXBIN. They are BASIC programs written for the 400/800 and XL machines, so they are excruciatingly slow. You really have to want to send a binary file to someone if you are going to use them! I never took the time to speed things up with machine language assist - anyone who wants to do so is welcome to it. (Please share your improvements with the rest of us, however).

The attachments below contain background on how BINHEX and HEXBIN work. The two messages which follow this one contain the Atari-BASIC source code for the two utilities respectively.

The most successful use of BINHEX and HEXBIN was for distributing the VT100 80 column terminal emulator last year. Little more has been done since then.

My apologies to everyone who has seen this stuff before - just toss it out as you see fit.

     Dan

Reply-to: Fleysher.wbst

Exchanging home-brew BASIC programs within messages over the net requires a modem and a good upload terminal emulator program (such as ATERM, distributed on the net in Oct. '82). Even with this set up, plenty of information can get lost in the transmission - e.g., inverse-video and graphics characters. Sometimes these are crucial when the BASIC program contains machine language assist in the form of text strings (rather than data statements).

I have written a pair of companion BASIC programs which enable the exchange of arbitrary files over the net with no loss of data. This is accomplished by converting the file to be sent into a text file containing hexadecimal characters, two for each byte of the original file. One of the programs does the conversion to hexadecimal format, and the other converts the received hex file back into its Atari-useable form.

Before I publish these two programs, I would like to invite agreement/disagreement on a standard format for exchange. The format I propose is:

```
--------------------
message header, explanatory
text, and general comments
.START.
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
xxxxxxxxxxxxx
.STOP.nnnnn
optional extra text
--------------------
```

The translator for the received program ignores all text until it

encounters the record ".START." Subsequent records contain hexadecimal characters (x's, above) in convenient (although unspecified) record lengths. The receiving program translates the hex characters into bytes until it encounters the .STOP. record. The number that follows ".STOP." is a decimal checksum, computed by adding up all the preceding bytes encoded as hex characters. (The checksum limit of 10 digits corresponds to a file length of more than 78 megabytes of average data)

My programs use record lengths of 36 hex characters so that they fit easily on the 40 character screen. Although the programs are written in Atari BASIC, there is no reason they could not be re-implemented as machine language programs (for speed). These could also be distributed to the net using this facility.

Needless to say, this facility is proposed for exchanging PERSONAL or public-domain software only.

Opinions anyone?

Dan

Subject: Exchanging Binary Files over the net
To: AtariUsers^.wbst
cc: Fleysher.wbst
From: Dan Fleysher <Fleysher.wbst>
Reply-to: Fleysher.wbst

Last month I proposed a standard for exchanging binary files over the net in text messages by first converting them to hexadecimal. That message is attached.

I received an excellent suggestion from ken@ROCHESTER to add checksums to the end of each line, rather than just the end of the document, in order to enable easier recovery. Unfortunately I haven't had the time to incorporate this change, but my experience has been that if I receive a message at all, I get it without errors 99.999% of the time. I also received suggestions to look at KERMIT protocol, but I already have an reliable underlying transmission protocol - the message system.

Consequently, I am distributing two BASIC programs - BINHEX & HEXBIN - that can be downloaded and used to encode and decode binary files to/from hex (text) format. Someday, I'll convert them to machine language and redistribute them (I apologize for the performance of the BASIC versions).

In the meanwhile, if anybody uses them and finds bugs or has suggestions, I would appreciate hearing about your experiences.

Dan

Help!!!!!!!
the past 3 weeks, two persons from nswc have tried to become members
of info-atari. requests have been made to info-atari-request@su-score
and messages have been sent to tang@mit-mc to be added to the list.
so far, no luck. the ids to be added to the list are:
     ecooper@nswc-g
and trichar@nswc-g

please help out. please respond to the above to addresses or
myself, bob hott at rhott@nswc-g   (arpa address)

thanks.

[... go ahead, eat my bits ...]

I've had several people ask me for the address of "Micro/Systems Journal"
that I mentioned in a previous posting, so thought I'd post it to the net.
M/SJ is put out by Sol and Lennie Libes (more or less out of their "garage")
as a replacement for the now defunct "Microsystems" magazine.

"Microsystems" was started by the Libes' back in the "early days" of micro-
computing as a *technical* magazine; "Micro/Systems Journal" editorial
content continues in that tradition. They're aimed at the CP/M and MS-DOS
technical community, but also have regular columns for UNIX, Turbo Pascal, C,
Data Bases, and the Scientific User. Two other regular features are columns
that cover current releases of public domain s/w: "PC/Blue Report" for the
MS/PC-DOS people, and "SIG/M Public Domain" for CP/M'ers.

Since their 1st issue, they seem to have picked up a fair amount of adver-
tising support (editorial/advertising ratio seems to be about the same as
Dr. Dobb's Journal has), and the technical content continues to improve.
If you're technically oriented, I think you'll enjoy the magazine. Best of
luck to Sol, Lennie, et al in this venture.

Here's the address:

          Micro/Systems Journal
          PO Box 1192
          Mountainside, NJ 07092

A sample issue is $4 ... $6 foreign.

	US	Canada/ Mexico	other foreign
Subscription rates are: 1-yr	$20	$28	$35
2-yr	$35	$52	$64

(US funds on US bank only, please)

Currently, they are publishing bi-monthly, and all their back-issues are available for $4.50 each, including shipping ($6 foreign). Back-issues can be ordered from the address given above.

Here it comes ... disclaimer: I only read the magazine, I haven't written for it, I don't own stock in it or advertise in it, nor am I affiliated with it in any other way. If anybody out there in net.land feels I am "commercializing" here, you are invited to send flames to the Tooth-Fairy :-).

All opinions expressed are my own, not those of my employer, roommate, or pet camel.

/kim

Yes, the Libes' DID start S-100 Microsystems; I remember getting my first
issue at the old Computer Mart of NJ. If the revived journal is as good
as the original S-100 Microsystems, then I sincerely wish them every
possible bit of good luck.

Regarding queries about and problems with the BYTE DOS for 256K, here's
what's in the MAAUG October newsletter:

[Start newsletter excerpt]

...the new Atari 130XE comes with DOS 2.5 which already supports a RAM-disk as D8:. DOS 2.5 will work with our memory upgrade without modification; however, since the 130XE only comes with 128K, DOS 2.5 has no way of knowing about the extra memory that our modification provides.

The following is a description of how to modify DOS 2.5 in order to provide D8: with a full 720 sectors (instead of the 512 sectors provided); and to add D7: with 720 sectors. This procedure is included for the benefit of other users groups... MAAUG members need not read this section since they can get the patched DOS at the MAUUG meeting. You will need an ASSEMBLER cartridge to install this patch:

1) Insert your assembler cartridge.
   Put DOS 2.5 in drive 1.
   Cold start your machine.

2) When the "EDIT" prompt appears, get into debug mode by typing: "BUG".

3) When the "DEBUG" prompt appears, get into the mini-assembler by typing "A".

4) Type the following lines ending each by pressing the RETURN key. The mini-assembler will respond to each line with one or more lines of assembled object code. Notice that you MUST type a space after each '<' sign (which denotes the end of the address and the start of the instruction).

```
B86< LDX #0
105C< LDA #$64
12DE< LDY $21
< CPY #8
< BCC *+4
< ADC #5
< TAY
< LDA $185B,Y
< JMP $1846
148D< CMP #6
14C4< LDA #$70
< JSR $1846
183A< .BYTE "MEM.SAV ERR",$9B
1846< STA $44
< LDA $D301
< AND #$83
< ORA $44
< STA $D301
< RTS
185B< .BYTE $20,$24,$28,$2C
< .BYTE $40,$44,$48,$4C
< .BYTE $60,$64,$68,$6C
77F< CPX #7
< BCC $78A
B88< CMP #7
< BCS $BD3
```

```
105E< CPY #$7
< BCS $1076
70A< .BYTE $C3
```

5) Press the RETURN key to exit the mini-assembler mode.

6) Type "X" followed by RETURN to return to the EDIT mode.

7) Type "DOS" to access the DOS menu.

8) Write the DOS files out to drive 1.

9) Turn off the machine and cold start DOS... when you do a directory of D8: you should now have 620 sectors free (instead of 499). Use the "I" command to format D7:. When you do a directory of D7: you should have 707 sectors free. (D8: is automatically formatted by the "RAMDISK.COM" program if present on the disk when DOS is loaded.)

10) Pat yourself on the back... you now have two full-sized RAM-disks.

Note: this patch will only drive 256K. A single patch to drive either the 256K or 512K will be forthcoming as soon as we have a working 512K memory upgrade installed.

QUIRKS

Don't erase DOS.DUP or MEM.SAV from D8:

Don't write DOS files to D5: thru D7:

Don't try to copy MEM.SAV

Don't count on the Duplicate disk function always working between RAM-disks

Don't turn off your machine and expect data written only to a RAM-disk to still be there when you turn it back on.

Don't run any 130XE programs that use extra memory without first saving any data that you need to keep from your RAM-disks to a real disk. (For example a sector copier.)

Don't expect all the 130XE software to work since there is one function of that machine which is not duplicated by this memory upgrade...namely, the extra memory video chip enable line (PB5) is being used by us as an address line.

Two DOS error messages were shortened/disfigured in order to make room for these patches. They are "Type Y to still run DOS" and "ERROR-saving user memory on disk". The latter now reads: "MEM.SAV ERR" and the former now is illegible (Asi es la vida).

If the 512K version of the upgrade is installed, then the self-test feature of the 800XL must be sacrificed.

Disclaimer: The information contained in the articles in the MAUUG Newsletter are intended for general distribution as the property of the Madison Area ATARI User's Group. The information is free and may be used in any way which is generally assumed to be appropriate by any individual or group of individuals as long as no financial compensation is incurred. Neither the articles nor the information contained in them is to be sold or distributed in exchange for money.
  ATARI is a copyrighted name and all of its products are protected by copyright.

[End newsletter excerpt]

Further caveats:
  Don't change your original copy of DOS!! Change a copy.
  There's a small chance that I confused a "B" with an "8" in the above instructions, due to the fact that the newsletter is done using a dot-matrix printer with less than perfect resolution.

Further news:
  The MAAUG now has a couple of 512K 800XL's.
  They are still having a few problems with the 1200XL upgrade, but they just started working on it last week, so I'm keeping my fingers crossed.
  I'm still trying to keep names of anybody who wants further info.

Personal disclaimer: I'm neither a hardware hacker, an OS wizard, nor an official representative of the MAAUG. Also, my employer has no connection with the MAAUG, and doesn't know what I do during my coffee breaks.

I seem to recall reading something about ST hard disk availability
in this group. Does anyone know what the story is (are they available
yet, what's the price like, etc)? Also, I'd be interested in the
quality of the C programming environment. Is the C compiler good?
Are there any Unix-like tools available (grep, make, lint (sigh))?
Thanks,

Isaac Dimitrovsky

Another esoteric bug!
If you drag a disk icon into a wall (easiest is straight up after positioning
on the bottom) very quickly it "lodges" there and the system hangs!

----Hey Rocky, watch me jam this here A disk into the ceiling ;-)

After it sticks, the system is locked forever...Spooky when you do it the
first time, but the you learn!

RE:
    " While there are a number of Atari Magazines available, may
I suggest that those interested in 68000 technology also look into
(and hopefully buy) 68 Micro Journal."

Here is a partially dissenting opinion. I recently subscribed to
68 Micro and was disappointed. Most of it seemed directed towards
the 6809 with relatively little on the 68K. If I had a 6809 system,
I'd probably like it more. As it stands, I'd rather read Antic and
Analog. Since I have a year's subscription, I should have plenty of
time to change my mind. (It does NOT seem to be a game of the month
rag, but more 'serious'.) I was interested in the 68020 single board
system ads that are beginning to appear there.

> CP/M Module
> 1090XL Expansion Box

I saw working models (prototypes?) of both a 1400XL and a 1400XLD at the 1984 Summer Consumer Electronic Show. That was the megabuck display just before WB sold Atari. The Expansion Box was also there as I recall but I wasn't really interested. The 1600XL was just a dream and never made prototype stage as far as I know. At least one of the 1400XLD and an expansion box was put to good use. It is the basis for the official Atari bulletin board according to an article I read (maybe in the Atari Explorer). Obviously, I don't have any of these for sale but I enjoy learning more about the history of Atari and thought you might also.

Keywords: In BASIC

Recently some implementations of UUDECODE have showed up in net.sources. One is for the IBM-PC BASIC, the other for UNIX C (We ported the last to the C86 compiler). If someone on the net is interested in porting these to something the Ataris' can use I will mail you the code.

I have read the requests of information about the Happy
software which is out. I have purchased a Happy upgrade for
both the 810 and 1050 drives. The 810 comes with the version 5.3
software and the 1050 came with version 6.6. The 810 and 1050,
using these versions respec{tively, will not communicate with each
other. Also, 6.6 does not come with Multi-drive. I was quite frustrated.
I wrote a letter to both Happy and the people I bought The kits from, both
of which responded to me quite rapidly. Both did state that Happy is
trying desparately to get the version seven updates out by the Xmas
holiday time frame. (This will please me to no end)
The version 7 will make the 810 and 1050 talk the same language. I
use the 1050 as drive 1, as the 1050 comes up and reads/writes at a
faster rate than the 810, and is also double density. The 810
runs as drive 2.

I must say, however, that I am quite "happy" with the drives, and
consider them far advanced over a "stock" drive for their basic
read/write speed improvements alone.

Although I know how much everyone hates those 'I want to know too'
massages, I ALSO WANT TO KNOW IF ANYONE HAS HOOKED UP THEIR HARD
DISK TO AN ST. (sorry) I really do want to know. If you had a 42meg
ST-506 type drive lying around you also would want to know. So thats
the reason I'm posting this. If you can shed any light on the st's DMA
port and the need circuitry to get a 506 type drive working on it
WE (I) would be gratful. Send mail. I summarize to the net. Thanks.

I have been working on a binary file ENCODE/DECODE package in ST Basic. The
language seems quite adequate, but I've been having a problem with my A: disk
drive. The disk seems to startup real slow and sometimes produces errors
(which Basic seems to ignore). Since it seems to occur only when I've been
running Basic (but I've done that a lot recently since I just got it), I don't
know whether I have a problem with the drive itself (a DS/DD drive which I'm
booting the system from) or whether Basic is trashing something which affects
access to the drive. Has anyone else had a similar problem?

By the way, the ENCODE.BAS program is completed and I have tested the internal
routines for DECODE. The program is similar to Unix's uuencode/uudecode but
provides for a line by line checksum. Multiple files can be encoded into a
single text file. I should probably finish a working first version this
weekend. I'll post it when I get decode finished.

Keywords: C 520st atari compiler SUMacC Mac

Has anyone considered setting up a set of librarys so that one could use the
SUMacC C compiler with the 520ST? I've been looking at and I believe it
wouldn't be too hard to do provided enough information was available on TOS
and GEM.

Is there a book out (or about to come out) which contains this information?
Is it available seperately from the developers package?

I posted public-domain versions of uuencode and uudecode to net.sources
several weeks ago; suggest you look there. You should be able to download
those sources, compile them on the Atari, and download uuencoded sources
(uudecoding them on the ST).

I strongly suggest this procedure over Kermit, Xmodem, or suchlike.

     Has anyone tried out the new MPP-1200AT modem from Supra (the old Micro Peripheral Products)? This is their new 300/1200 Baud, Hayes compatible modem that uses the SIO port on the 8-Bit computers. It lists for $249 but Computer Games + has an add in the 12/85 Analog magazine and lists it for $199.95. The Omega Terminal software for it is supposed to be extreamly versitle as well.
     I'd be interested in any information on this.

> Why not hope that the new 68000 machines will push IBM out of the market?

NObody is going to push IBM out of the market. The best you can expect is
that it'll light a fire under them. It's almost enough to make you want
to nuke Armonk.

     Try calling Happy's information number at 408/779-3830. The revision
7 software and the 1050 controllers are not quite ready but all orders re-
cieved by December 15 should be shipped by the end of December. The add in
the 12/85 issue of Compute! was a little premature.

Summary: Transfer formats.

     There are many hexcode formats around. I'd like to suggest Motorola 'S' file format. It might be possible to standardize on this for 68000 machines.

I originally posted the following to net.news.group only, but it does address
a point that needs to be made... to wit, that while UNIX implies portability,
portability does not imply UNIX.

> The Mac is not UNIX. There is not one relatively standard compiler that
> everyone uses. #ifdef's just don't cut it, because the compilers are very
> different from each other. The idea of distributing source only is,
> frankly, stupid, and people who have programmed so little on the Mac that
> they would make such a suggestion should not be going around pretending to
> be experts.

Well how about getting together & doing something about making these radically
different languages pull together a bit more? Over in net.amiga there has been
a little discussion on trying to write programs that can be ported easily
between the AMIGA, the ST, and the MAC. If the MAC can't even port to the Mac
not only does this cut Mac users out of this game but it hardly makes the Mac
look like a real computer... for the rest of us or not. If what you say is
true and unavaoidable I've just lost most of my considerable respect for the
Macintosh and its user community.

After all... ifdefs do cut it everywhere else. It's possible with a little
work to write a program that can compile and run on the IBM-PC with a variety
of compilers, VMS, *and* various semi-compatible flavors of UNIX. The same
program, mind you...

[On further consideration... this would definitely make a useful net.software.
project. Someone might even get a paper on "porting programs between radically
different environments" or something. Hey, Ken, ever considered porting curses
to the Macintosh? :->]

>   net.micro.atari16 for Atari 16 bit machines
>
> Similarly if either Commodore or Atari come out with 32 bit machines, then new
> subgroups could be established.

As I understand it, the 32-bit Atari will also be an "ST", and that it
will have a similar architecture to the 16-bit Atari. (For example,
you can bet damn well that a 32-bit 386-based IBM pc will be MS-DOS
based.) If the new commodore is not an Amiga, no harm is done.

The current system works just fine. (People used net.micro.mac to talk
about the Lisa, and nobody complained.) Because enough other things
are broken, there should be a bias for status quo barring some great
overriding requirement.

Has anyone else purchased the Word Magic/Graphic Magic programs
listed in the ANTIC catalog? I am not on this mailing list, so I am not
sure if they have been mentioned before. I got these 2 programs
a week or so ago. While the advertisement which states "functionally
equivalent to Macwrite/Macpaint" may be true in the sense that you
can print text and graphics on the same page, I am a little disappointed
with the way it happens. You have the option of printing a 1/2 or 1/4
page reduction of a graphics screen created with Microillustrator,
MicroPainter, etc., and you have to save the screen with the Graphic
Magic program. The 1/4 size option is not too bad - it is reasonably
fast and takes up around 97 sectors on the disk. 1/2 screen size
is another story - it uses over 430 sectors and takes about 4 minutes.
Neither of these sizes allow text to be placed on top of the graphic,
although this is advertised as an option and is in the manual which
comes with the program. You can place text on top, but it is printed as
garbage. There are several other things I don't like about the program,
but I guess for 19.95 you can't expect much.

If anyone else has these 2 items and knows that I am doing something wrong,
please let me know.

---------- bug eater here ------------

Has anyone out there been able to get
STwriter to print single-spaced copy?
I have tried all sorts of variants of
ctrl-S, etc. without success. I use
an Epson FX-80 on the serial port,
screen dumps and system prints are fine.

Secondly, Atari has shipped the first of their
hard disks for the ST. No reviews yet, but
stay tuned.....

Finally, Will Hom, I've tried them all...
No joy. Please add dlc@aerospace to your
Atari mailing list.

Tom,
I don't know which serial numbers have sockets. We have never seen an 800XL
that didn't have the RAM socketed, and that is the most important thing
for the 256K upgrade. Did the 800XL you returned not have the RAM socketed?

We have been shipping the 256KXL for a couple of weeks now and no problems
have been noted. It makes the 800XL look exactly like a 130XE except that
bits 5 and 6 of $D301 have been redefined to address twice as much memory.
I have also souped up a version of OMNIVIEW XL to treat this extra memory
as a double sided single density ramdisk.

You are right Richard, OMNIVIEW does use GR. 8 to generate the characters.
However, it looks better than the others I have seen because I did a lot
of work on my character set. Most people report that they are quite pleased
with the readability. This technique also has the great advantage that it
is cheap! That is why my sales are better than ever and the others are out
of business.

One other advantage to this technique is that you could theoretically mix
text and graphics on the screen. I have not yet had time to try this out
but maybe eventually ...

I enjoy reading your well thought out comments,

David Young

Has anyone seen Atariwriter + in any comuter (or other) stores yet?

Am anxiously awaiting it, no one locally seems to have any idea when it will show up, suposedly Atari has been shipping it to distributers and is filling up the pipeline.

I just had to say that I agree with everything you said. The IBM-PC was good for its day, but now it is stiffling real innovation, along with the other 8088 based products. The only thing we can do is hope that as people become more computer literate, they'll realize that segmentation is a limitation, along with other things. Lets hope the new generation of 68000 based "personal computers", ie, Atari 520ST/TT and the Amiga will help push IBM into new hardware approaches that won't cost the consumer his/her shirt in order to buy it.

>   And
> remember that the IBM PC was technically advanced compared with what was
> available when it entered the market. Evidently a lot of people find
> the machine (along with third party hardware and software) sufficiently
> useful to buy it. Moreso than any other personal computer.

While in general I agree with most of the things he said, I do take issue
with the relatively 'technically advanced' comment. Olivetti produced
a z8000-based micro which was 'technically superior' in my opinion. (Of
course, I worked at Olivetti (in Cupertino, CA) so what do you expect? :-)

The IBM PC was a hit in the marketplace because IBM made it a hit. Not
because of any technical superiority.

Has ANYONE been able to create a double sided boot disk yet????
If so, how....And don't give me the way you think it MIGHT work!!!
I'm interested in finding someone who HAS ALREADY DONE IT.

I tried copying the boot sector from a single side to a double sided disk,
but that crashes the directory and capacity info....After patching those
tidbits back, it still won't do it.....What else am i missing?

> there is an OMNIVIEW made for every ATARI 8 bitter except the 1200. In
> addition to 80 column output, they all have other features including
> resident ramdisk handlers.
>.....etc....
> David Young

How come my local computer store seems to think that they can install OMNIVIEW on my 1200XL (as well as my 800XL and 130XE)? Since you developed it, you should know. Do you personally produce it or does some company produce and market it? If so, have they developed it for the 1200XL independent of what you did?

Also, besides giving 80 column capability, what are the other features? What else does it do for you? How legible is Omniview using composite video? Separated video? I have seen an Atari 130XE using separated video on a C*******e 1702 monitor and it looked great, but it was not using 80 columns.

Finally, is there anyway of using an RGB monitor with an 130XE? And if so, would this work with Omniview?

Obviously, at this point in time, I am shopping around for: a) a good monitor and b) 80 column capability. I had the impression that you could use a RGB monitor with the 130XE (but not with the 800XL or 1200XL) but I am getting the impression from some of the magazine articles that you can indeed use RGB with the 130XE. However, I am not about to put out the bucks for RGB if the 130XE cannot use it or is just as good with separated video.

Thanks in advance,

Bill Dippert

I've currently upgraded a 1200XL to 256K using the article from the
september issue of Byte. Their upgrade covered the 800XL. Now, here's
the problem. When we run Ramsgl or Ramdbl and format a drive, the
screen turns to blue and white horizontal stripes from top to bottom.
The rest of the computer works fine, it's just when we try to access
the extra ram for ramdisk that it seems to fail and lock-up. We're
using the source code mentioned in the Byte article, and I feel that
may be the problem. Has anyone else made this upgrade to the 1200XL?
Any assistance will be greatly appreciated. Once we get a working
machine, I'll summarize and post. Thanks again.

Oops! I deleted the original posters name. Sorry.

>I have a problem calling OMNIVIEW an 80-col board. (Please correct me
>if I am wrong, DY...)   From what I understand, OMNIVIEW is not a full
>character 80-col generating board, but rather an 80-col SIMULATION in
>GR.8. Meaning 4-bit wide characters....acceptable but NOT genuinely
>(in my view) an 80 column board.

You've hit upon an important topic that all prospective 80 column board
purchasers should be made aware of. I've seen some of the GR8 based
"simulations" and they are pretty awful, even on my 900 line resolution
monitor. Actually, the resolution of the monitor is not important anyway
since these "simulations" really only produce 3 pixel wide characters (you
have to have 1 pixel of space between characters).
After squinting at pseudocharacters for about 3 hours, you'll see what I mean.
The only real solution is an adjunct to Atari's graphics/video using a
real character generator ROM or a higher resolution bit-mapped display.
Is this what the rumored RGB/80 column board used before its demise?

The resolution is limited to 640 pixel horizontal, but the character set can
be reconfigured, and it is possible to cram 132 characters on a row, but it
looks funny. Also the screen has too many verticle lines. Hard to read as well.

This is a test to see if the messages that I have been posting to
net.micro.atari have actually made it to:
     a) other computers within Tektronix
     b) the outside world
     1) ARPANET
     2) USENET
     3) other

I would appreciate some response with an indication as to which catagory.
If there are at least one response to each catagory then the test is
terminated and no further responses are necessary.

Thanks in advance.

Summary:

(munch)

 I would still like to obtain one of those 1200 keyboards. Can anyone supply me
with the address of a source. Maybe the phone number of that Radio Shack where
some of you got yours.

What kind of inducement can I make to get a reply?

If there is interest I could post a method of adding cursor control keys that
don't need to have control pressed. My current external keyboard had cursor keys
so I added a little hardware to make them work normally. The method can be
extended to add a whole pad of custom keys. (insert,delete characters....)

     Well, I though I might have overlooked it via 'c'atchup, but I've since noted that the message you refer to didn't arrive at 'lsuc' until after I had posted my response. Usenet is interesting in that way. You can't expect everbody to read everything when you do.

     Up here in Canuckland Atari's never really sold well. You must remember that Toronto is where Commodore was Born. This accounts for the fact that TPUG (Toronto Pet Users' Group) is the world's largest Commodore Users' Group (as I understand it, then now run the Commodore SIGs on Compuserve -- which as I understand it hasn't worked out that great for some reason). Until just before Tramiel bought u
out Atari, I rarely saw 800's of any kind, except in magazines and
ers' Distributing).

     Your card is new to me. Good news though.

                                        Cheers! -- Jim O.

There is a wonderful article on the ST sound chip in the November issue of
Antic. Patrick Bass (ST editor) wrote a small sound program for testing
the chip, and he includes a beautiful table for the chip itself.
I don't know if that will help you because the program is written in "C".

My problem is that I have Hippo-C and I believe all the ST programs in Antic
are written in DRI-C. One question: Is there a math library (sin,cos,random)
for Hippo-C?

Aloha,

The following is an enhanced version of the bouncing ball demo for the
ST, it was written by Jim Eisenstien of Atari. It is well worth looking
at to see the full power of graphics on the ST.

I was one of the purchasers of the Austin Franklin 80-column boards (about 2 years ago, as I recall. I had ordered and received one board but was sucessfull at getting it working only for about 1 hour. (The board "died" shortly after.) As I recall, the images were very clear and readable on my monitor. I don't have the documentation at hand, but I think that the characters were somehing like 6 or 7 pixels wide.

Austin Franklin Associates went belly-up shortly after I received my card and therefore, I was unable to secure repair or refund of my purchase price (approx $300) from the company. And AF Associates wasn't willing to provide schematics so that I could troubleshoot my board. So I sent the board back and went through the legal procedures for getting my credit card company to refund my purchase price and go after AF Associates. (I did eventually receive a refund thru my credit card company.)

The board had a direct video output (to the monitor) and (I assume) used some kind of FET switch to change from standard Atari video to 80 column video.

I have been a user of the Omniview for about 1 year now and find it to be a very good product. Yes, the characters are a bit difficult to read and I'd rather use a terminal if its available. But the Omniview is a very clever modification to a machine that was never intended (by its designers) to be an 80 column text machine.

After a long edit session, I attempted to copy my file to another disk, and SURPRISE! TOS trashed my disk! I've lost every thing on that disk and it's been a very long time since I backed it up.

Has anyone out there written some code to fix frazzled disks (like the Norton Utilities for the PC)? I'll pay real money. Thanks in advance.

Terry,
You say that you have seen some of the 80 column simulations and that they look pretty awful. I agree. But it is not so much due to the lack of resolution available in graphics 8 as to the poor character sets these authors have created. I have studied calligraphy and I think that as a result the character set of OMNIVIEW is quite nice. And I know thousands of customers that would agree. Of course there are certain letters like 'm' and 'w' which you can do nothing about. But then again, with a good monitor there is no doubt what these characters are when you see them on the screen. And I strongly disagree that a good monitor does not make any difference. It makes all the difference in the world, especially when the difference between 'm' and 'w' is only one pixel!

Besides all of this, I doubt very seriously that you will ever again see any other 80 column hardware for the 8 bitters. Given the price of the machines it is just not cost effective. And OMNIVIEW gives you so much more than 80 columns! I just finished souping up the ramdisk handlers in OMNIVIEW XL/XE to treat the extra RAM in our 256K upgrade for the 800XL as a double sided single density drive. What a joy to have such a big ramdisk!

Steve,
That 256K RAM upgrade in BYTE was a real dog. We have got a 256K upgrade (256KXL) that will make your 1200 130 compatible. You can buy it without RAM for $50 or with for $100. The reason that the BYTE upgrade is such a dog is that it ends up including the stack in the bank switch area. Worthless!

I've posted the source for a communications program for the 520ST on net.sources
The article title is 520ST COMM. This program allows unlimited save
of ascii text to either printer or disk. It will also transmit text
files. The user can and should specify a transmit delay time before

file transmission. This insures that the receiving host can keep up.
Minimal error checking is performed in the program. This program is
not a final version, but it does work fine at 1200 baud.

[]
After playing with the machine this weekend, I found out some interesting
facts, and minor TOS bugs which I thought I would pass on here.
[]
1) Ever get TOS error 2? It means you're trying to delete a read-only
file...Do a show info and change the status.

2) Don't make a folder with EXACTLY 8 characters...TOS flakes and may make
the disk unusable.

3) Don't create more than 99 items on a disk (not too hard to do on a
double sided drive)...The system mushrooms.

4) Don't have two directries open at the same time that are close to full.
Mushrooms again.

5) Don't let the DESKTOP.INF file get too full. It appears that after about
600 or so bytes, it mucks up the world (result of installing too many
applications). In that case, delete it and start all over.

6) Problem with double sided boot disks? I found you can't just copy
from a single side and patch the sector count and side count.
There is also a checksum at the end that must be calculated for it to
be valid!!!!!   Oh, for decent flow of information!

[]
I'd appreciate hearing any similar tidbits from others, hopefully BEFORE
I crash into them!

     Rob Botwin, N2FC

I am also interested in how readily converted the 1200XL is. My understanding from some of the previous posting is that the group in southern California is converting 800XL's commercially and that they are compatible with the 130XE. This is what I really want -- 256K 1200XL and 800XL that are totally compatible with the 130XE. I do not think that the source code mentioned in the Byte article does this -- am I correct in my thinking or am I wrong? Also, does not the 1200XL use a somewhat unique OS? I never saw any differences in what programs that I ran, the 800XL and the 1200XL seemed to run the same programs equally well, but the AMODEM4.2 program that would run on both the 1200XL and the 800XL will not run on my new 130XE so there is something different about the XE's. (Probably having to do with their use of joystick port B (the non-existant joystick ports 3 and 4 are used somehow for the access to the additional RAM locations.)

Is there anyone doing the 256K modifications in the Portland (OR) area? If so, publicize how to get ahold of you. Thanks in advance!

>It just did {CC, that is}; the December issue is the last, although Ahl et al
>are looking for a 'white knight' to buy the rights from Ziff-Davis &
>start them up again.

Yep, ol' Ziff-Davis ought to be pretty proud of their hit-ratio ... lessee:

    Microsystems
    Computers & Electronics (formerly Popular Electronics, and one of the
                oldest hobbiest/tech magazines in the field)
    Creative-Computing

Anybody know who published "PC Age" ... one of the few technical magazines
for MS/PC-DOS'ish machines a year or two ago?

Granted, the Marketplace has changed over the years, but I suspect that there
are at least as many people interested in technical info now as there were in
(say) 1978 or so ... actually, I'd bet that there are quite a few more.

It couldn't possibly be that these magazines just weren't turning *enough*
profit to satisfy "Corporate", could it?

BTW, Sol & Lennie Libes have resurrected Microsystems (which I believe they
started, before Ziff-Davis got ahold of it), and renamed it Micro/Systems
Journal. They've just published their 5th issue, and are running it out of

their garage. It has a very high percentage of TECHNICAL/editorial content,
and deserves to be successful. If you haven't yet tried it, pick up an
issue ... if you're technically oriented, I think you'll like it.

As an example, their 5th issue included the 1st half of an extensive article
on the NEC V20/V30 chip (pin-compatible, but higher performance replacement
for the 8088/8086 chip), including alot of assembler macros to use the new
opcodes, etc.

Note: I'm not associated with Ziff-Davis (obviously) or Micro/Systems Journal
      in any way, and my opinions are my own ... though the Tooth-Fairy often
      agrees with me.

/kim

I am planning to take a monochrome ST to Europe, but am concerned with
possible compatibility problems. While the voltage problem can be
easily solved, it is unclear to me what the implications of 50Hz
line frequency maybe, for the power supplies or the monitor.
Can anybody give me advice on this ? Thanks in advance.

OK folks. I have heard a bit about the 1/4meg upgrades for the
800xl (from the BYTE article, followed by some mentions on this
list), a modification of it for the 1200xl, versions of each that
are compatible w/ the bank select scheme of the 130xe. What about
the old 800 (no letters)?. I am currently working w/ a friends
Axlon RamDisk. This scheme is NOT compatible w/ the new XE scheme.
The RamDisk is NOT mine & I would like to have something of my own.
Has anyone come up w/ a do-it-yourself memory upgrade for the original
Ataris? One that matches the newer XE bank select scheme? (One that
matches the XL scheme for 64k RAM?)

Anxiously awaiting replies (will summarize to net if enough),

Fellow CP/Mers - Occasional postings of messages offering or announcing items for sale have caused some flurries of (sometimes) heated debate concerning "proper use" of the Defense Data Network, through which INFO-CPM is distributed. I believe that most subscribers to this list honestly wish to adhere to the "network rules" and not jeopardize INFO-CPM's use of the DDN. But although the policy regarding personal "for sale" messages has been clearly stated many times (they're not allowed), it has become quite obvious that the lack of a clearly stated policy concerning new product announcements is causing much frustration to those who wish to post such information while still "playing by the rules". Therefore, this message states my interpretation of the regulations, and presents a resulting policy to which I, as INFO-CPM list maintainer, ask all DDN subscribers to adhere. I also ask that contributors to "NET.MICRO.CPM" on USENET voluntarily cooperate so that the mutually beneficial news gateway between INFO-CPM and NET.MICRO.CPM is not threatened.

The June 1984 issue of the "DDN Directory" gives on page 12 the following statement concerning use of the network:

> "The DDN is an operational DoD network and is not intended to compete with comparable commercial service. It is intended to be used solely for the conduct of or in support of official U.S. Government business."

It is the vagueness of the term "official U.S. Government business" that forces a local interpretation to be made, and that is the reason for this message.

Briefly stated, my policy is this:

1. I offer to act as a clearinghouse for all new product announcements posted by persons having remunerative interests in the products. Persons wishing to post such announcements are asked to send them to INFO-CPM-REQUEST@AMSAA.ARPA for forwarding to the list. Please note that this applies ONLY to "remunerative interest postings". Readers having no such interests are always welcome to send comments about products, new or old, directly to INFO-CPM.

2. Messages offering personal items for sale must not be posted.

This policy is explained in more detail below.

PRODUCT ANNOUNCEMENTS: I feel that the information value of a product announcement must be weighed against possible personal rewards when making a decision about use of the network. There are many government-owned computers running CP/M, and on which serious government work is being done. Several years ago, the DARCOM Microcomputer Software Support System (DMSSS) project was instituted, with one of its aspects to provide a repository of public domain software on the net. INFO-CPM was sponsored as the official vehicle for announcements of the status of the collections, and to promote the interchange of user information on the use of CP/M and the programs which run under it. This is why INFO-CPM is "in support of official U.S. Government business". New products that provide improvements to the CP/M operating system, to associated utility programs or to the machines on which these programs run offer productivity increases to government users. Therefore, it is in the government interest to distribute factual information concerning such products. Still, when an individual having a personal monetary interest in a product posts an announcement concerning that product, it raises questions about "commercial use of the network".

Therefore, as I have no involvement with any provider of CP/M-related products or services, I offer to act as a "clearinghouse" for all new product announcements being submitted by persons having remunerative interests in these products. I ask that all individuals wishing to post such announcements via INFO-CPM send them to INFO-CPM-REQUEST@AMSAA.ARPA. My requirements for relaying such messages to the list are:

1. They must be of general interest to the "CP/M community". Products that address specific subsets of this community, such as those which operate with or on an "XYZ machine running CP/M 2.2" meet this requirement.

2. They must be brief and factual, listing the salient features of the products, and giving brief explanations of the techniques used to achieve improved performance (if applicable). In short, they must be INFORMATIVE.

3. They must be free of advertising hype - no superlatives. Comparative words such as "better" and "improved" are OK provided brief explanations are given as stated above.

4. They should include the name and netmail address of a person to whom requests for additional informaton can be directed, or a statement that no additional information is available if that is the case.

I will not attempt to present here an all-inclusive, "iron-clad" set of rules, as I do not believe it can be done; and if it can, I don't know how. Please send any questions regarding this matter to INFO-CPM-REQUEST@AMSAA.ARPA, and NOT to the entire list. If further clarifications seem necessary, I will update and resend this message.

PERSONAL "FOR SALE" MESSAGES: I think there is a very significant difference between product announcements and personal "for sale" messages.

Products that are offered to the public which provide new capabilities, or which improve the performance of existing systems offer these same benefits to government users. But personal deals are "one-on-one", and unless the buyer is a government user (which I consider an extremely remote possibility considering the "red-tape" associated with procurement), no benefit can accrue to the government. Therefore, personal small-volume offerings violate the intent of the rules and should not be posted.

REPLIES TO POSTINGS: Please make intelligent decisions regarding replies to product announcements. If such a reply is of general interest, then feel free to send it to INFO-CPM@AMSAA.ARPA (i.e., to the entire list). I will include with each posting the address of a person to contact for additional information (or a statement that no further information is available, if that is the case). Please send non-general-interest replies PRIVATELY to the person listed, and NOT to the entire list.

If a personal "for sale" message does appear in INFO-CPM and you wish to respond to it, please do so PRIVATELY and not to the entire list. If your mailer can't send private replies, then DO NOT REPLY at all.

I would like to thank Jeff Edelheit, Frank Wancho, Bridger Mitchell and Jim Guyton, as well as several local BRL people who do not read INFO-CPM for their participation in a "behind-the-scenes" discussion of this subject. We had a spirited but fruitful argument that helped greatly in clarifying the issues and in arriving at the above policy, which I believe is responsible and responsive to the rules for network use.

The above policy has been coordinated with the Army Ballistic Research Laboratory personnel responsible for monitoring BRL's network access, through which INFO-CPM is delivered to the DDN. This message will be repeated periodically for the information of new readers, and to refresh the memories of others. Your cooperation will help to insure the continued existence of the INFO-CPM newsgroup.

I don't think there IS a way to POST binary files. The best I can
suggest is an upload to the archives at simtel-20 and/or su-score
(if either of them are being maintained currently, I know the simtel-20
archives are active w/ cp/m software, but whether anyone accepts atari
software for the micro:<cpm.atari> directory is another question.)

The other suggestion is to post the source, or a basic program w/
a read/poke loop & data statements. You can write a short program
to create a basic loader from a binary file fairly easily....

>I blew it when i posted jim's code to do the bouncing ball, can someone help
>me ? how do you post binaries ????

There is no established method for doing this for all the possible readers of
this article. For folk using Unix, you could post using uuencode to convert
the binary into a text form. This can be converted using uudecode under Unix
and downloaded using the binary mode of Kermit, PC Intercom, Modem, or what
have you. Unfortunately, those who don't have Unix probably don't have access
to uuencode/uudecode.

If nobody comes up with something soon, maybe I'll brew something up which
will run on the ST and post the sources in C and/or ST Basic.

I am looking forward to seeing the ST version of the bouncing ball demo, just
to see how close it is to the Amiga demo.

>-------

Just a few more tidbits (from DEC's _Guide to Personal Computing_):

   DIGITAL made quite a sensation in 1960 by announcing the first "personal"
   computer, the PDP-1.

> The PDP-1 was different in another more important way. Users could change its programming midstream and "talk" to it through a simple keyboard. It answered by displaying messages or data on a small video screen or by typing on a printer. [Ed. note: What a concept!] The PDP-1 was the first commercial computer to offer this capability.

It also has a picture, which looks sorta like a heathkit product from ten years ago. Interesting.

Recently there was some discussion of possible 80 column display upgrades for the old ATARI computers. I recently purchased a RAMROD os board and along with it an OMNIVIEW 8k chip. This chip resides on the RAMROD os board and creates an 80 column display via software. The program resides in the 4k of memory that was previously not accessable. It is compatable with BASIC and can be activated either with a usr call or by hitting a sequence of the START, SELECT, and OPTION keys. I have been using it with AMODEM4.2 communications software and it has been working well. A switch was provided that allows going from 80 column mode to a resident monitor that has features such as program interupt, dissasemble memory etc.. It even came with an 80 column text editing package. One note however, since the 80 column emulation is done with the high res graphics mode, 8k of ram is consumed by the program, also a monitor is needed for quality characters.

    I recently got one of these clunkers because it was a real cheap
    letter-quality printer that I could connect w/o an interface box.
    It comes with NO information about features except for how to
    print an international character set. Does anyone know if it
    has any other features?

The only other feature it supports is underlining. The paltry
information it contains tells everything there is to tell.

As promised, here is a list of some of the xbios() calls which
owners of the Hippo-C compiler may wish to use. Since I don't know
much about the Hippo I can't promise that they will work as listed
here (I've heard that the Hippo int size is 32 bits?). Oh well,
good luck!

```
/*
 * If Hippo-C has no xbios() call available, you may be able to
 * get away with the following:
 *
 *       .text
 *   _xbios:  move.l   (sp)+,.temp   ; get return address
 *       trap #14      ; trap 14 is xbios
 *       move.l   .temp,-(sp)   ; push return address
 *       rts           ; return to calling program
 *
 *       .bss
 *   .temp:   ds.l          ; temporary storage
 *
 *
 * In this document, the following definitions are assumed:
 *
 *   char = 8-bits
 *   int  = 16-bits
 *      long = 32-bits
 *
 */

/* long Physbase()
 *            Returns the address of the screen's physical
 *            base at the beginning of the next vertical
 *            blank.
 */

#define Physbase()  xbios(2)

/* long Logbase()
 *            Returns the address of the screen's logical
 *            base immediately.
 */

#define Logbase()   xbios(3)
```

```
/* int Getrez()
 *            Returns the screen's resolution (0, 1, or 2).
 */

#define Getrez()    xbios(4)

/* VOID Setscreen(log_addr, phys_addr, rez)
 * long log_addr,  Set the screen's logical location (log_addr),
 *   phys_addr;    physical location (phys_addr), and resolution
 * int  rez;       (rez).  Negative parameters are ignored,
 *            making it possible to set one parameter
 *            without affecting the others.
 */

#define Setscreen(logaddr,physaddr,rez) xbios(5,logaddr,physaddr,rez)

/* VOID Setpalette(palette_ptr)
 * long palette_ptr;   Set the palette register (all 16 colors)
 *            from the 16 ints pointed to by palette_ptr.
 */

#define Setpalette(palette_ptr) xbios(6,palette_ptr)

/* int  Setcolor(color_num,color)
 * int  color_num, Set the palette number "color_num" to
 *      color;          the given "color".  Returns the old color (if
 *            old color is negative, no change occured).
 */

#define Setcolor(color_num,color) xbios(7,color_num,color)

/* long Random()
 *            Returns a 24-bit psuedo-random number.
 */

#define Random() xbios(17)

/* char Giaccess(data,reg_num)
 * char data;      Read or write a register on the sound chip.
 * int  reg_num;   "reg_num" is the affected register, ORed with
 *                 $00 to read
 *                 $80 to write
 *            "data" is the byte to write to the register.
 */

#define Giaccess(data,reg_num) xbios(28,data,reg_num)
```

I hope these will help some of you out there. Remember to make sure that all of your ints are 16-bits (let me know if I'm wrong about Hippo's int size).

As a poor (read that any way U like) British subject I have to interface
with Dig. Res. about ST problems.

Their British support arm stinks. They really need a good shot of deoderant.
There was a joke in a Unix mag about unix support staff who could not destinguish
an I-node from a tree-toad. That is these guys through and through.

To the point. Have any of U over there with a developers kit got any better
support than I have? If so who is Ur contact and what does it cost?

I have found the C compiler to have numerous code-generation bugs (try
```
     struct {char x,y} z;
     ...
     if ((--z.x)<'9') {
```
and U get real crappy code (BCD operations actually). Does any stateside
good-guy have a bug list for this compiler ? Should we start one ? Am I the
only person using DR C ? [I have a list of about 10 different code generation
funnies if anyone wants them]

All comments welcome

Jon Malone

There has been a number of claims as to who originated the term
"personal computer." The following is an excerpt from an interview
with Alan Kay by Kevin Strehlo, which appeared in Computer Currents,
The Bay Area's Own Computer Newsmagazine, Third Year, Number 11,
page 37:

     Strehlo: What's the impact of IBM being so important in
              personal computing?

     Kay: I think there are two things to think about. One
              is that they haven't made a personal computer yet.
-->   I was the one who made up the phrase personal computer,   <--
              and they haven't made one. One of our tests for
              whether a machine is a personal computer is whether
              people would be willing to do anything so mundane as
              to put their grocery list on it.

Also in this interview, Alan talks about Project Bivarium. He envisions
building animal-like creatures that you send on missions, such as finding
information out of a network. Perhaps one of his creatures will stumble
upon this message someday.

Because of many reasons, including money and J. Tramiel, I will not
buy an st. I don't want to see st messages. Splitting the group would
hurt no one, as those (like Bob Halloran) who want to see both sets of
messages can get on both lists, while those of us who see 10 messages
a day on a computer they'll never buy won't be bothered anymore.
Seriously, folks, fully half my mail is about a machine I'll never
get. Splitting will have the advantage of getting us a moderator
again.

This open letter is NOT concerned with whether the 520ST is better or
worse than the amiga: I feel that both are very interesting machines
which might either flop or sell a lot. It IS concerned with that nasty
subject of END-USER PRICE, in particular for those of us who live in
Europe.

As an indicator of the problem, consider the following prices for the
Atari 520ST (floppy, mouse, monochrome) :-

In the USA $600-700

In England	$1000	(+15% VAT)
In Switzerland	$1400	

Obviously I do not yet have figures for the Amiga in Europe. I do know that in the past the Commodore European prices have not been outrageous compared to US prices.

Now, I know that there are all sorts of arguments why prices in Europe are higher than the US prices, and why Swiss prices are still higher. However, I buy sufficient amounts of computer hardware to have heard all these arguments many times, and my empiric observation is that a markup of above 10% (England) or 20% (Switzerland) is excessive. Please don't waste my time trying to argue otherwise.

Therefore, the message to Atari and Commodore is as follows:-

If the Commodore markup is anything like the Atari markup, then the Amiga will be priced around a Mac. As such, it will lose out simply because of the volume of software already available for the Mac. Also, of course, it is then more expensive than the IBM PC: same arguments. However, if the markup is very small then the price might be around the current 520ST price. So, Mr Commodore, please minimise this markup as soon as you start to sell in Europe.

If the Atari markup stays so ridiculously high then it will not be much below that of cheap PC clones (or even perhaps the Amiga). It will certainly not be in the right range for the Home Computing market: note that this market is only now starting in Switzerland (lots of C64s on sale, educational programs on the box etc.). People will start getting 520s in funny places, modifying them locally, and there will not be a tidy organised selling operation. Therefore, Mr Atari, please tell your European distributors to be less short-term greedy and more long-term intelligent.

I hope that these words might help people like me, who envisage upgrading their current home computer next year, but don't know yet with what!

Summary: Programmed Data Processor

In article <8511052150.AA19797@ucb-vax.berkeley.edu>
D-ROGERS@EDWARDS-2060.ARPA writes:
>> IBM coined the term personal computer.

> I hope to shout! How about the PDP-1, PDP-8, & PDP-11 by Digital
> Equipment Corp. The PDP stood for "Personal Data Processor" and was
> probably the first standalone interactive computer that didn't require
> massive resources needed to support a mainframe.

From an artifact on my wall, printed by DEC circa 1969:

> Programmed Data Processors 8/S, 8, 9, 10 and the LINC-8
> are general purpose, stored program, digital computers
> capable of a wide variety of data processing and control
> functions. The PDP line spans the complete spectrum of
> on-line, real-time applications ranging from simple data
> acquisition on the "8/S" to a full-scale time sharing
> facility on the "10".

Note "programmed", not "personal".

There have been personal computers since the early days. Consider the
Bendix G15 or the LGP-30. In fact, becoming "impersonal" was a definite
sign of progress: it made bigger machines economical by allowing them to
be used efficiently. The new personal computers are a sign of further
progress: hardware is cheap enough that a useful configuration can be
dedicated to serving one person.

If I remember correctly, the term "personal computer" was used before
IBM entered the market. But it was not the dominant term. People often
called them "micros", "home computers", or "hobbyist machines". I think
that the term "personal computer" is more apt now.

By the way: there seems to be a lot of animosity towards (read:
"unreasoning emotion against") IBM and it's PC. As a UNIX user, I
regret that the marketplace has made the IBM PC such a success, almost
smothering innovation. The effect is premature standardization. It
will be very hard to wean the market from a very low level standard:
8086 machine language, BIOS calls, memory mapped video of specific
capabilities at specific addresses, etc. Contrast this with my UNIX
experience: over 10 years, I have often changed hardware (PDP-11,
VAX, 8086, 68000, 32000, proprietary) and UNIX version (5th, 6th, 7th
edition, 4.1, 4.2 BSD, System V, XENIX 2, 3) without leaving my programs

behind; some transitions were painful, but none were fatal.

But IBM did not make its PC the standard, the marketplace did. And
remember that the IBM PC was technically advanced compared with what was
available when it entered the market. Evidently a lot of people find
the machine (along with third party hardware and software) sufficiently
useful to buy it. Moreso than any other personal computer.

  >P.S. Have any of you necrophiliac 8-bit Atari users seen the latest
  >Lucasfilms software (Eidolon?) yet? Is it worth owning?

I have not played this game personally but I saw the preliminary version
running at the Consumer Electronic Show in June and all the reviews I
have read have be good. They use fractals to generate the walls of
tunnels (you are underground most of the time) and the animation is very
good. If you like graphics adventure games with an arcade touch, you
will like it.

In regards to the 8-bit machines, I don't think they are dead. Atari is
continuing to build them (at least the 130XE) and they are selling. Best
of all software manufacturers are continuing to write products (both games
and productive type) for them. Many of the hardware types are still
actively involved (CDY Products, to name one good one) and many of the
stores that carry them are run by Atari enthusiasts interested in more
than just selling straight available products. One example is CAL COM INC.,
in Silver Springs, MD. I don't know them personally but a look at things
they sell shows they are enthusiasts, not just a store. Where else can
you buy a 130XE with an extra 128K installed (they call it the 327XE) or
a 130XE with OMNIVIEW already installed? And there prices are very
reasonable (520ST monochrome package = 699.95, color = 849.95 and the

130XE = 135.00). They even list the 1 MEG upgrade kit for the ST for
$200. As long as places like this exist and User Groups keep spreading
the word, the 8-bit machines will continue to be a viable product. We
have at least 13 people here with Atari 8-bit machines, probably half
of which bought them because of the first users talking them up.
We can make a difference. If someone that doesn't have a computer
starts asking questions, are you quick to point out the advantages of
the 8-bit machines or do you say 'wait a while, the ST's are out and
I'm sure the price will drop'? Face it, most home users don't need
the capabilities of the ST. Sell them what they can use now, they may
eventually want to move up.

I didn't mean to carry on so long or preach but I hate to see comments
like 'the 8-bit machines are dead or out-dated'. It simply isn't true.

Alan Kay seems to get credit for a lot of ideas. It has been my
experience that ideas are often created and developed by a team while a
few individuals get away with claiming all of the credit for them. Alan
Kay seems to be living off his reputation - has anything he has done at
Atari or Apple made those companies any money?

From my experience just about everything is more expensive when
imported. Just try and buy a BMW or Mercedes in the USA and see
how the price is inflated (even allowing for US emission controls).

The Swiss are probably just trying to recoup all the taxes levied
to run the navy .... :-)

I am the proud owner of a 8510 Prowriter printer. I do however, have a

few questions which someone out there might be able to answer for me with their infinite wisdom:

1. What is the type of chip and at what board position does it reside, for the additional RAM chip which may be inserted to give one a 2K internal printer charachter buffer.

2. What is the procedure to create and download a custom charachter set to the printer.

I thank you in advance. Mark (I thank you in advance.

Summary: Converting Color Computer Boards?

     I don't know how practical this suggestion really is, but the Radio Shack Color Computer has a number of second source 80 column boards available for it. If the signals are sufficiently compatible you might be able to convert a Color Computer 80 column board via jumpers. Check a copy of "The Rainbow" and you should be able to find a few. I use PBJ's Wordpak which is based on a 6845.

     I thought there were 80 column boards available for the Ataris? Whoops! Sorry, I'm thinking of Commodore 64's.

                                        Cheers! -- Jim O.

Summary: Not Byte

I think that you've misheard. Byte's not folding. Creative Computing apparently is folding. Furthermore, Popular Computing is folding and apparently Hot CoCo is folding (although I expect Hot CoCo will be absorbed into 80 Micro again). There may be others biting the dust too fairly soon.

One magazine that is still going is 68 Micro Journal. If you're interested in the 68000 processor family, this magazine will probably be of value. Right now it's mainly 6809, but covering OS-9, Flex, C (at a fairly advanced level). I'd hope that the next year will bring Atari support as well, but it's hard to forcast. The Mac never seemed to develop much interest in this magazine, but then the Mac was never promoted as a 'hackers' computer.

Cheers! -- Jim O.

Keywords: software, reviews

Anyone here read net.movies? Mark Leeper occasionally submits movie reviews,
and although I don't necessarily agree with him, I do enjoy reading them.
They are well written, and provide a coherent picture of how Mr. Leeper
feels about the movie.

I think it would be useful if some of the people using the new 520ST programs
would review them and provide facts, impressions, limitations, etc. of the
operation of the program. I wouldn't necessarily require that they be
objective, just systematic and coherent. They should provide useful
information for those considering the purchase of such a program.

So... If you've got that software and you love it or hate it enough to say
something about it, then go ahead, let us know. You might save someone
from wasting money on bad software, and you might save someone a lot of time
by pointing them towards the right software. I've never owned software
that I haven't had a firm opinion of it's usefulness. Speak up!

You got it wrong I believe. Europeans (companies especially) do not
think it respectable to pay a little for a lot .... There must be something
wrong if it that cheap mentality ....

If the AMIGA doubled it european price many people would start to look at
it MUCH more seriously.

Its a strange world.

sorry - it just will not work under HIPPO-C. Unlike the 'C' that comes
with the development system, HIPPO-C passes everything on the stack as
a 4 byte quantity - thus calls which expect objects of size < 4 will
not execute correctly. For example, the setscreen call will not
execute correctly as the resolution parameter must be passed as a WORD
value on the stack.

While I'm here.... I'd like to check something out with ST developers
on the net. A TTP program gets passed argc/argv on the stack, this
stuff is read from the base page before the task is fired up. HIPPO-C
will generate a .PRG file but it does not set up the stack properly for
the call. Is there a way to get the base page back after a .TTP program
has started up?

Lines: 16

I am trying to interface a Panasonic KX-P1091 printer with an
Atari 800XL via the 850 interface board. When I try to print
documents (using Atariwriter) in the Near Letter Quality mode,
I get unexpected spaces and some repetition of text. I am not
using any special drivers.

Does anybody have any experience with the 1091 that might help
me decide whether I have a printer problem, a compatibility
problem, a bad cable, other!!!!

Please send information to:

I'm an 800 owner, but am considering getting an ST sometime in
the future. I DO want to hear about both, and would do this by
getting both 800 and ST distributions if there is a split. Since
a split does let everyone get just the stuff they're interested in,
the only real argument against it is whether it's harder to maintain
two separate (smaller) groups. Can we find two moderators when we
can't seem to find one?

*** ***

   With the price of 1200 baud modems plummeting, I'm considering getting
a modem for use with my 1200XL. The only problem is that I'm totally
ignorant about what is needed for interfacing. This is exacerbated by
the lack of local stores that carry Atari equipment. I'm assuming that
an RS232 interface is needed, like an 850. However, the 850 seems both
overly expensive and overly scarce. So, I'd like to either find a cheaper,
more available interface, or find out where to get the information necessary
to build my own interface. I'd appreciate any help anybody could provide.
Email please; if anybody else is interested, let me know and I'd be glad to
give you what I've got.

I recently purchased a IBM PC with a RBG monitor.
I would like to be able to use my Atari 800 with this monitor.
Does any body out there in netland know of any way to convert
the atari's composite signal to RBG?

Thanx in advance.

I agree with Kit Kimes wholeheartedly that the 8 bitters are far from
dead! Based upon our ever lively sales to old 800 owners (not to
mention 800XL and 130XE owners) I would have to say that people are
planning on keeping them around for a long time to come. And why
shouldn't they? They are more machine than most people will ever need.
Of course, many people like to spend their money trying to keep abreast
of the latest technology. That's fine. Good luck!

There *were* some 80-col boards for the OLD Atari 800 (non-XL/XE).

The most infamous was BIT-3 80-col board. There was another reviewed in
Analog at one time that produced a COLOR 80-col display (RGB even....).
I forget what company put it out.....

Why the "oops... I was thinking about Commodore" afther the "I thought
Atari already had an 80-col board"???

Keywords: ST PC/InterComm PF Keys

<Mmmm, tasty>

Does anyone (maybe at Mark of the Unicorn) know how to define a PF key
in PC/InterComm with an escape character in it. When you hit the escape
key, InterComm jumps out of the PF key definition section to the menus.
I couldn't find a way of (escaping?) the escape key. It sure would be
nifty if you could do that (hint, hint).

Jim O.,
     You sure make some outlandish statements. Why should anyone want
to kludge around a Radio Shack 80 column board when there have been 80
column outputs for the ATARI for years? One which I developed, OMNIVIEW,
was described just a few messages back by Kim Kimes (sp?).

This message is to clarify Richard Hartman's message and to fill in a couple of holes. First of all, it was Kevin Meis who did a review of OMNIVIEW a few days ago. Thank you, Kevin. Just let me point out that there is an OMNIVIEW made for every ATARI 8 bitter except the 1200. In addition to 80 column output, they all have other features including resident ramdisk handlers.

The other 80 column board with RGB output was the Austin-Franklin. The people who have this board seem to really like it but it wasn't around for very long.

Both ATARI and Batteries Included had both announced plans to come out with 80 column boards but have since dropped them. I am proud to be the only survivor in the 80 column world!

In all fairness I must mention another 80 column output that I have heard of but not seen. Called the ACE 80, it resides in the cartridge address space and works with Letter Perfect and Basic. I don't see how this can be very useful since it takes up so much memory space (OMNIVIEW resides out of the way in the $C000 page). Besides this, I would not be surprised if it is not a ripoff of OMNIVIEW. If I am wrong, somebody please correct me.

Keywords: sound 520st wave ST-BASIC envelope

Having just received my copy of ST Basic, I've been writing some short
programs to play with the built in sound chip. The manual page for the
"wave" command is missing the table of various envelopes available for the
sound chip. Does anyone have such a table handy?

I HAVE figured out a few combinations. For example this gives you a nice
"ocean wave" effect:

wave &h8,&h1,14,30000,1

Is it possible to set up two or three *seperate* envelopes? One for each
voice perhaps? Is I read the manual I don't think you can do it from basic,
but perhaps you could "poke" the settings into the chip?

Yes, there was a BIT-3 80 column board for the old 800's. It used to sell for about $200, but I've seen it discounted to ~$120 just recently. Speaking of the old 800's, I recently purchased one for a christmas present for a friend (only $69!); when I hooked it up to see if it worked, I noticed a vast improvement in the video output (as compared to my 800XL). My software driven 80-column terminal was actually (barely) readable on my AMDEK color plus monitor, and *perfect* on my little NEC 9" monochrome. The XL's video on the monochrome was readable, but a little fuzzy. What gives? Do I have a dud XL, or is the 800 supposed to have higher quality video? How about the 130xe?

Uh... I ran it on my ST and got 849 Dhrystones/sec. Did you use the DR C compiler, or the Haba C compiler? I used the DR C compiler that comes in the development system.

Even so, we're still cranking out twice as many dhrystones as the Amiga...

>programs to play with the built in sound chip. The manual page for the
>"wave" command is missing the table of various envelopes available for the
>sound chip. Does anyone have such a table handy?

You might try looking at the Nov. 1985 issue of ANTIC magazine. There is
a pretty good article about the sound chip and how to use it from C. The
information about the chip is applicable to ST Basic usage also.

>Is it possible to set up two or three *seperate* envelopes? One for each
>voice perhaps? Is I read the manual I don't think you can do it from basic,
>but perhaps you could "poke" the settings into the chip?

After looking at the article in ANTIC I am inclined to say that the chip only
has the capability for one envelope. You would think that if it has three voices
the designers would have given it three envelopes. Sigh.....

What is the current status of memory upgrades for the st?

A while back, there was some traffic about homebrew upgrades
and 3rd party bareboards. How are these working out (any
overheating problems) and how about software compatibility problems?

Also, is there a good magazine for st articles and ads? (I'm
coming from the Apple][world and not familiar with Atari land.)

Thanks.

I have a problem calling OMNIVIEW an 80-col board. (Please correct me if I am wrong, DY...) From what I understand, OMNIVIEW is not a full character 80-col generating board, but rather an 80-col SIMULATION in GR.8. Meaning 4-bit wide characters....acceptable but NOT genuinely (in my view) an 80 column board.

There is a PD communications program called VT10SQ (vt-10 squared, or VT100) which also uses a software 80-col display. I also pulled a file from a local BBS which seemed to contain ONLY the E: (or was it S:?) wedge from this program.

Possibly this 4-bit charset technique could be used on the 520ST for the person desiring 132 columns. (Actually you could get up to 160-col on the ST with this.)

The 80-col RBG board (someone supplied the name...but I didn't even try to remember it) actually generated a full 8-bit wide character, 80-column display (you needed a RGB monitor, of course...) I believe the BIT-3 board did the same for a monochrome monitor.

If any of this is incorrect, please feel free to reply....

-Richard Hartman
max.hartman@ames-vmsb

BTW: Does anyone on the net actually have one of the previously mentioned RBG 80-column boards (Austin something just popped up in my memory...)?

You can definitely play tricks to get large numbers of colors visible
simultaneously. Neochrome 0.5 (a very good color paint program available
free from Atari to any ST purchaser) shows around 200 colors at once
in its color selection area.

>This would, in the long run, benefit Apple itself!
>   ... Whereas the "MAC-like User Interface" may have
>soon become the industry standard, displacing anything put out by IBM or
>Microsoft, Apple has now forfeited that position.

I just have to put my two bits in on this one. Apple has nothing to gain and
everything to lose by letting the "Mac-LIKE user interface" (emphasis mine)
become a standard. The hordes of business computer users who think that IBM is
the only name in computers have no reason to buy Apple products unless they are
in some way clearly superior to IBM. This superiority can be in price,
features, performance or what have you, as long as it's enough of a DIFFERENCE
to make up for lack of IBM compatibility. If the "Mac-like user interface" is
available on the IBM PC, short-sighted grey suits will see no reason at all to
buy a Mac. Thus, Apple (as a profit-making business) has no choice but to
protect its differences.

This article reminds me of those who said in 1980 that IBM's entry into the
personal computer field would "legitimize" the industry. (Remember when "PC"
meant "a personal computer", not "an IBM-compatible 16-bit MS-DOS computer"?
Remember Osborne and Victor? Remember when micros were an adventure?)

I've directed followups to net.micro.pc only. This branch of the discussion
is taking off in an IBM-compatible direction.

By the way, what DOES that .signature with the two tombstones mean?

David D. Levine   (...decvax!tektronix!teklds!davidl)   [UUCP]
                     (teklds!davidl.tektronix@csnet-relay) [ARPA/CSNET]

P.S. Forgive me for spouting off, but it looks like I'm going to be forced
to use a PC at work (can you imagine the pain of using MS-DOS every day when
you're used to the power of UNIX?) and the very thought of IBM just makes me
sick.

>times as fast as the 68000. (Today's buggy National chips are roughly
>68000 speed +/- 30%, and their future ones don't touch the 68020.) If

Apparently John is unaware of the NS32332 which provides 3 times
the performance of the NS32032 putting it in the same ballpark as
the 68020. It will be available in December 85 (Yes, this one is on
schedule!) and also has a leg up on the 68020 in its memory interface
because it supports currently available dynamic rams in nibble mode.

This becomes important when you get clock rates up around 15Mhz.

Cory Barker

PS. Yes, the 32000 series does have a few minor bugs left in current
revisions, however I would not refer to them as buggy. The 68020 on
the other hand...

I think that the person who sugggested that the Apple/DRI suit is due
to Apple's not wanting a "second rate" desktop to represent the genre
might have some merit. Point: they have NOT (as far as I know) started
action against Amiga's "Intuition" interface. (On the other hand, they
could just be greedy, and will get around to Intuition, Windows, et. al.
soon enough.....)

              -Richard Hartman
              max.hartman@ames-vmsb

P.S.: This does not mean that I think GEM is second-rate (or first-rate
      for that matter). I have not used it. The term came from the
      msg to which this is a reply.

No one has yet offered any response to my challenge! We are particularly
interested in seeing how the Atari does on this benchmark, given the
preponderance of subjective claims foating around.

I hope someone can take the time to run these and post the results,
rather than continue to fan the flames of speculation that flood
these groups. I can only assume that they have not yet appeared because
no one has bothered to do it, rather than because of the results they
achieved. Of course, I have been known to be wrong on occasion...

*** ACE WIT SAGE ***

   Over the past few months, I've been searching for a good technical reference guide or two for the 8-bit Atari's (I own a 1200XL). Two books that were recommended are "Your Atari Computer", by Lon Poole, and "Technical User Notes" (author unspecified). I've scoured the bookstores and computer magazine ads, but haven't found anybody that sells the first, or can get the second (Computer Palace, in Eugene OR advertises the latter, but in fact doesn't have it and can't get it). If anybody knows where I can get either of these books, I'd appreciate a pointer (e-mail, please). Also, is "De Re Atari" a good book to own (I currently depend heavily on Compute!'s "Mapping the Atari" for all my info)?
   Also, while I'm here, I own a Indus disk drive, and want to order both the new DOS (with "Synchromesh") and the DOS Reference manual. All around both the documentation and software, they say things like "Write or call us... we'd like to hear from you!"; the only problem is that they don't give a telephone number or address. If somebody has that handy and could e-mail it to me, I'd be eternally grateful.

>An ST developer locally (Users group) said that Atari had just liscenced
>SYS-V Unix from AT&T. Can anybody confirm?

Computer Systems News reported the licensing this week.
According to Tramiel, UNIX will be available on the 1024ST (which
will be packaged with a hard disk) and a NS32032 based machine.
No offering for the 520ST will be made; "more powerful hardware"
was said to be required, presumably a memory management unit.

Now let's see them bring one out for $1500 in six months....
then I'll be happy!

"I'd like one of those, please..."

1) You don't make money by giving away your product.
2) IBM would have NEVER advertised their product as "Mac-compatible"
That would have made them appear to acknowledge a peer, which,
in their eyes, they have none.

>something like that got posted and people started using it then the people
>responsible would take action to correct it.

Consider yourself lucky. Every message that leaves the USENET from ucbvax
bound for an ARPANET mailing list has two headers added to it:

     Sender: usenet@ucbvax.berkeley.edu
     Errors-To: usenet@ucbvax.berkeley.edu

I'm usenet@ucbvax.berkeley.edu. Imagine my mailbox.

If a mailer is implemented properly, it should send error messages
back to the `Sender:'. `Errors-To:' is something that sendmail knows
about, which I insert as insurance.

The offending systems that have been incorrectly routing error messages
back to the USENET poster are all TENEX/TWENEX systems. I encourage you
to bombard the mailbox

     postmaster@offending.arpa.host

for each error message you receive. If you (and others) lambast the
individual postmasters sufficiently, perhaps they will in turn poke the
mailer implementer(s) to FIX the damned things. Among other odious
behaviour exhibited by these mailers is that they will try an address
for three days, and EACH DAY they will send an update if the message
has not gotten through. Personally, I only want to know when my message
finally fails. Before that, I don't want to hear it!

I'm not talking about photocopying or otherwise ripping off a legitimate
copy. I'm talking about writing a program from scratch that behaves almost
exactly like a copyrighted program and then placing my program in the public
domain. Like if I wrote an MSDOS that was 100% compatable and then said
hey world you can have it for free.

While on the subject of keyboards. WHERE DID ATARI GET THE IDEA FOR
THOSE (&@#$@#$%#@ SLANTED FUNCTION KEYS? They may LOOK "futuristic",
they may be GREAT for those who use their left hands to select them,
but they are a real PAIN for those (like me) who try to use their
right hands! Why not SQUARE buttons? (For that matter, why are they
all up in one row w/ NO seperation?......maybe the pushing two keys
problem would go away if they weren't slanted.....)

When will Atari learn that ergonomics means more than appearance

NOTE: I don't know WHO this should be sent to, but the current
      msgs floating around on the INFO-ATARI list prompt this
      reply (*** FLAME ON ***):

From what I understand, USENET people are complaining about the
errors that they get from foriegn mailers when something goes
wrong w/ a msg they post.

1) This happens to ARPA people to, you are not alone so don't
   feel persecuted.

2) Who SHOULD the error reports go to? Not all mailer problems
   occur in "mailing-list" situations. If I send a msg to an
   Oregon USENET computer through the UCB gateway, >I< want to
   know that it didn't get there, so I can re-send it! Why
   should the UCB postmaster be bothered with something he/she
   neither known nor cares about?

3) As far as I can determine, at least SOME of these errors are
   consistant. Meaning that it wasn't just a host down somewhere,
   we are trying to send msgs to people whose accounts no longer
   exist. I believe that AT LEAST some of this problem would
   be alleviated if someone just ERASED the "problem" addresses
   from the mailing list. (I have NOT had this problem w/ INFO-CPM,

for example....)

Sorry about the flame guys, but it had to be said. BTW: If any of
my assumptions are wrong, feel free to reply. But maybe we should
stop sending this stuff to the INFO-ATARI list?i

Attention:

     If any electronic "bombarding" is attempted I will guarantee that
your mailbox will be filled with 100 megabytes of mail. The right
"fix" for the problem is to have somebody maintain INFO-ATARI again.

     I am sorry that UUCP is so primitive. I consider myself fortunate
not to have to use it.

I'd believe this if they didn't say they were going after the AMIGA next (which
they have been quoted as saying in InfoWorld). The AMIGA is in no way a bad
implementation of the desktop metaphor. Of course no-one is going to switch
to a Mac once they get their hands on an AMIGA either. I just wish the AMIGA
icons didn't look so hokey. Time to pull out the old binary editor.

I'd like to ask about Atari vs Amiga Graphics. I saw an Amiga last night, and although I thought it was pretty nice, it didn't quite seem to be all it's cracked up to be. I thought the graphics were slightly fuzzy (maybe the monitor), and the Gem desktop fonts were hard to read. Maybe it's the color combinations, I don't know. I'd like to have either one of these machines, but I want to text to look crisp.

Has anyone here actually compared the ST and Amiga side by side, both color and black and white graphics? How does the Gem disktop look on the atari? Opinions please.

Hello,
I have started a new Atari mailing list. It will be run in the same fashion as Hacker's Guild. For those of you who are unfamiliar with Hacker's Guild, it is a mailing list that deals with advanced topics on Unix,C

or anything in general. Well, my mailing list will deal solely with Atari machines, both the old 800 series and XL's and the newer ST series. The format of this mailing list is as follows:

(1) Anyone can send in questions or comments about any Atari related item into the mailing list.

(2) Anyone can respond or flame the individual if he so chooses. In this way, some of the more experienced Atari users can help some of the novices and neophytes with questions.

(3) This list will also disseminate some of the rumors about Atari. (i.e. spread gossip about the happenings in Atari land)

(4) I will also describe some projects that some individuals are working that are Atari related.(i.e. hard disk development, battery backup for the ST clock, hooking ST's to 5 1/4 inch drives and reading IBM format data disks,...)

(5) Announce any new developments in the way of software, hardware,...

Of course, I won't do all of the above all the time. You also have the chance to send in any Atari tidbit or program source for some program that you have been working. Looking toward the future, (if this list survives), I am thinking of starting some tutorials about advanced topics such as DLI's(Display List Interrupts), Player Missiles and so on for those who are new to Atari computing or just want to learn.
If this list does take off, I will plan to distribute these tutorials to only those who request it so as not to miff the advanced users.
I am still looking for someone to send in a question or comment. All I have received so far are a lot of requests to join.

If the volume of mail suggests this, I may have to send this list out as a digests. If that happens, I will try to lump all questions about such and such into one giant letter.

That reminds me. If you would like to join the list please mail your requests to :

(ARPA) mail-atari-request@ucbugs.Berkeley.EDU
(uucp) ...!ucbvax!ucbugs!mail-atari-request

If you would like to mail any articles to the list, send them to:

(ARPA) mail-atari@ucbugs.Berkeley.EDU
(UUCP) ...!ucbvax!ucbugs!mail-atari

If you get your mail returned from one of the addresses, please send it the other.(i.e. If your mail is bounced back from the ucbugs acct., send it to the requests address(ucbseymour). Ucbugs is a flaky machine and it goes down every once in awhile for no reason, hence the name ucbugs.)

I hope this answers any questions concerning the list and I await a load
of mail from Atari users and enthusisasts!

Will Hom

The reason we can't follow your suggestion is simple. A mailing list
like ours is a simple reassignment of names; my name and the names of
the other arpa readers get put in a recipient field, and you are still
the sender (Which is why I can reply to you now.). This is fine for
small groups, as no one has to go through the hassle of moderating the
list. Any mail you send is exactly like sending n messages, one to
each person on the list. You would get a message from the appropriate
mail demon if one of those messages were unsuccessful in getting to its
recipient, and judging from your complaints, this is indeed what has
been happening (Believe me, from a list this size, be glad there are
only eight irresponsible individuals who didn't tell anyone when their
mail addresses changed!). This format was really designed only to
work for a small group. I am on and run several such groups, one for
my living group and its alumni, one for an experimental program I'm
in at school, etc. each with less than 100 people on it. It would be
a real pain to readdress each message 80 times by hand in order to get
to those same people, though. Using this format for a large list,
especially one spread out over the country, is going to run into some
trouble of the sort you just described. That is why there are
digests. Digests are simply all the messages sent to the list put in
a single (long) mail message, so that the recipient can "undigestify"
them and read them. A typical digest will go out two to ten times a week.
The benefit is that the person who "digestifies" (digests?) the
messages is the one who resends them to the list, and is thus the one

who receives all the mailbounce. The problem is that someone has to do a LOT of work (this list would require a new digest every 2-4 days).

This arpa list is of the first kind, which gets us messages faster, but has obvious drawbacks. For one, we now have NO moderator, as Mark Crispin stopped some while ago, and no one has stepped forward to take his place. This means that there are no changes being made to the file containing our names. I have been trying to desubscribe for a month now, without success. It would be quite possible (and quite nice) if someone wrote yet a third kind of mailing list program which would do as you suggested -- automatically send out a message FROM info-atari-request TO (everyone on the list) each time it received a message TO info-atari; not unlike an automatic single-message digest. That way, mailbounc would go to info-atari-request, and the moderator could handle it there. This is indeed a part of a program called pmd (personal mail demon) which is written in C and runs on any system which looks for a .forward file before putting mail in someone's mailbox (e.g. any system running sendmail). A friend of mine wrote pmd, and I will send copies to anyone who wants one.

Unfortunately, since we don't have a moderator, this won't happen for a while, so all of us (including usenet recipients) will have to suffer a while longer. This brings up your last suggestion. DON'T START A MAILER WAR! What will happen is this: you send a message into the net. 3 machines work for a few days trying to send your message, and send back one refusal message per day (all the others copies of your message get to us). That's nine messages you get back. You resend those messages to the "offending machines" (which are only doing their jobs). Each machine works for three more days trying to send the messages...you get 27 messages back. Your phone bill will blow up before the machines will. If you send to postmaster at those machines and complain, they will tell you not to expect mail to be delivered to nonexistent addresses, and they HAVE to return it (arpanet requires it). The source of the problem is not at what you call the "offending machines", but on our list and the way it is (isn't) being run. The only solution is to FIND A MODERATOR! I can't do it, because I don't have the kind of storage capacity necessary to hold the archives, and frankly, I want to get off this list.

An arpa-arpa mailer war can bring (and has brought) down the Arpanet in a disastrous way. An arpa-usenet mailer war will kill the usenet recipient with phone bills long before the arpa machine dies from overload. If you bounce your bad mail to the machine the list is on, most likely it will slow things down there (as well as load up the list, which you receive) and the people using that machine will complain and the list will go away.

There are two immediate solutions: 1. suffer (i.e. accept the mailbounce as the cost of posting.) or 2. don't post. I don't like it (think: I get 8-15 messages a day that I don't want, whether or not I post to the list!), but aside from writing to postmaster@score and telling him to completely kill the list (BAD IDEA!), we're stuck.

I was not suggesting bombardment, just rerouting of mail messages so that they go to the person(s) responsible for all the junk mail. Look at it this way: Due to incorrect management and/or software, many megabytes have already been sent to the wrong people.

UUCP may be primitive, but it is the arpa sites that are exhibiting the brain-damaged behavior. Being fortunate is a matter of perspective.

I must say that I find it quite hard to believe that NatSemi is already coming out with the 32332 already, when they haven't even come out with the 32132 or the 32232 yet(Yes, these are actual scheduled components).

This argument is moot anyway for one reason. The 68020 is considerably faster because the original 68000 is very bus bound, while the 20 is much less so. On the other hand, the whole NS series has a prefetch queue etc. and so speed differential between any of the components is much less. Also, a memory cycle on the NS series and the 68000 is 4 cycles, as opposed to the twenty, which is 3 for main memory, and 2 for the 256 byte queue.

Would you like anymore?

Summary:

I recently asked Sam Tramiel about the rumour that AT&T was negotiating
to sell 520STs under its own label, and he said that was not true.
Then he said, "But we are negotiating with AT&T, and they have several
520STs. We are going to license UNIX...for the ST series and our
second-generation (TT series) computers."
Tramiel said Atari plans to have 1-meg and 2-meg ST machines in 1986.
Back in June he had told me the TT computer(s) would definitely use
the National 32032, but this time he said Atari still was choosing from
among 3 chips. He wouldn't comment further.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***
its twue, its twue and i can hardly wait, atari will be porting SV to an
upgraded 520 (more memory) and there is talk about a full port (with
virtual memory) to an 68020 based unit which will be an "add on" to the 520.

Wait a minute: "GEM is not a good product"? People using GEM won't buy a Mac?
What drivel! I've just spent a month evaluating GEM, and the GEM toolkit, and
beg to differ. GEM offers a desk-top metaphor user interface management system
to the PClone world. Last year, when I finally decided to buy a personal
computer for myself and my family, I bought a PCjr, not because I could run
GEM, but because it would run most of the software I had purchased during my
years in manufacturing engineering and as a college student. The fact that
GEM was available never entered into it. The typical GEM user picked it up
AFTER they already owned or had access to a PC or clone thereof. While I do
not like the layout of the toolkit, (I prefer an object oriented approach), it
is in many ways similar to that of the Macintosh. The appearence of the
desktop is the largest similarity to the Mac, and is the only thing in question.
If Apple employees are saying that GEM is inferior, then they should look at
their own problems as well. The underlaying toolkit, as mentioned before, is
similar. When I say I prefer an object oriented approach, I mean that I would
prefer that the underlying tools would be object classes. But the Mac and GEM
toolkits both provide a procedural interface, which in turn forces the resulting
interface to be more internal than external. GEM is a good product. As an
experianced computer user, I am happy with a command line interface. I have
been evaluting TopView (c IBM) as well, and MUCH prefer GEM. I use GEM when-
ever I have a lot of file copying or moving to do. I usually fire up GEM,
then escape to the MS-DOS command. I may then use the command line interface
as I wish, yet can use the GEM goodies by simply typing "exit". I agree with
a previous poster that Apple would be better off allowing desk-top metaphor
products on non-Mac hardware. Such a strategy would lead to wide acceptance
of such user interface management systems. I have little doubt that Apple
is in a better place than any one else to further the state of the art in
such UIMS's, and if they would spend more time being the inovative company
I have always thought of them as, and less time bitching about imitators,

they could become the industry leaders they think of themselves as.

I have no interest in whether Apple products are superior to IBM products or DRI products. I choose what I buy based on the greatest functionality for my money. I would hope that most other people do the same. Instead of trying to provide functionality, over the last two years or so, Apple has instead chosen to provide hype. I sincerely hope they get back on course!

Summary: I can't answer briefly

In article <190@ucdavis.UUCP> ccrjohnm@ucdavis.UUCP (John McLaughlin) writes:
>It seems like ~ 30% of the mail in the net.micro.xxxx world these days
>is made up of discussion of the OS9 operating system. What is
>so special about OS9? note that I am not saying it is not a good Operating
>System , I just have never played with it, and I am curious as to why
>it is being hyped so much.
>
>
>   John

I think this is a good time for me to say that I've had a lot of enquiries via mail which I wanted to respond to and haven't yet. I just can't say anything that's brief and complete enough. I have a file which is a compilation of things I've posted to BIX. I just haven't had a chance to upload it from my main OS-9 system to my Unix connection (right now due to a small bug in my terminal program I can't send a straight ASCII dump properly. I have to XModem it to my CP/M system and then ASCII dump it to lsuc--all at 300 baud).

Another problem is that I can't seem to 'mail' to everybody. A fair bit of it seems to get returned.

In fact, If Bob Larson reads this, I hope he sends me a voice phone number so I can call him. I've sent messages to him via 'mail' and some gets through, but I think some of it didn't.

At any ragte, I'll see if I can post something in the next few weeks. (But if somebody else wants to, then don't wait for me...:-)

Cheers! -- Jim O.

Would you claim that the micro industry would be be better off if
IBM had not come in? Think for a moment of all those builders of
IBM clones. IBM has very nutritious coattails. Apple may or
may not have been wise in suing DRI, but they would almost certainly
sell more Macs if IBM made one just like it than they do now. [Note
to flamers: it's just my guess against yours, but I don't mind if
you really insist on telling me why yours is better.]

Personally, I think an obviously Mac compatible interface, available
for the IBM, would be good for Apple's visibility in corporate
offices and that it's better to be perceived as a technological
leader, willing to share your insights with the rest of the industry,
than as a miser, jealously guarding the insights you stole from
those who preceded you. Which, rightly or wrongly, is the way a lot
of see Apple.

>< and the subject is : GEM is second rate? so apple sues?

what?

Apple is suing because (according to apple) GEM presents the exact
look and feel of the MAC interface. Obviously if GEM were second rate,
it would present an inferior look and feel compared to the MAC.

Consequently, Apple would have no case.

And anyway, the line of reasoning by the original poster was wierd.

Apple sues because this inferior MAC clone hurts keeps people from
buying MACs? I'm not going to buy a Chevy because the Ford was a piece
of junk? What? It is because GEM is an excellent windowing desktop
environment, available on aggresively priced PCs such as the ST that
has scared Apple into monopolistic restraint of trade activity.

That's a necessary attitude on Usenet, where mail may take two weeks
to arrive at its destination. Perhaps the Arpanet people, with
continuous connectivity, are used to mail performance that makes
a one day delay onerous.

For those of you with Percom drives for the Atari...

if you ever call Percom (in Texas) and ask about repairs, don't believe them
when you are told the ONLY place in the U.S. that can repair Percoms is in
Falls Church, VA. That's what I was told. But after calling around a few
places in the Detroit area, I found a store that will repair mine, no problem.

One of the great attractions of the ST environment for me is, that it possible to go beyond beginner mode into knowledgable user mode. This is in stark contrast to the Mac, where I am either forced to relentlessly click dialog box after dialog box to get at some effect I should have been able to express from the keyboard in a couple of strokes. In a lot of the ST application software, you don't have to click a quit item in a menu if you don't want to, Control C works too. Unless I've been royally ripped off, I'll only be a beginner on the machine for a little while: I'll be a wizard for years to come.

Everyone I know who uses mouse-based computers or workstations, whether they be LISP machines, graphics work stations, or home computers, quickly home in on the "California" mode of use: left hand hovering over the keyboard, right hand on the mouse.

Since I bought the Atari ST in July, people (programmers, really) have been trooping through my house playing with it, and I have been struck by the uniformity of response. Everyone who works with Xerox 1108s or

Sun workstations think the keyboard is very well designed: everyone who works with vt220s or 3270s grump about the slanted PF keys.

I think this is another instance in which Atari made the correct choice: the slanting is only annoying for a short break-in period, and a great convenience after that.

Ergonomically yours,
Bill Henneman

I thought the same thing that others have stated when I first saw the funtion key design for the ST. How are you supposed to hit the right key when they are slanted like that? But, I haven't had any trouble hitting the right key. They work fine for me. What I don't like about the keyboard is that there is no place to rest the heals of your hands while you are typing. The keys starts right at the edge of the keyboard.

John

> preponderance of subjective claims foating around.

Not all benchmarks are created equal...

Perhaps not everyone responds to a challenge in the same way -- I tried the
given algorithm (Lattice C and my own library) on my IBMPC and found that
my IBMPC:
```
     writes a 32K file in   14.28 seconds
     reads a 32K file in    13.45 seconds
     /*  all times given for standard floppy disk  */
```

However, if I twiddle my disk buffers around, my IBMPC:
```
     writes a 32K file in   14.28 seconds
     reads a 32K file in     2.96 seconds
```

This led me to rewrite the algorithm to take advantage of the many layers
of disk buffering I use:

```
     write(fd, p, 0x8000);  /*  the hard way...  */
     read(fd, p, 0x8000);
```

With the new algorithm, I find that my IBMPC:
```
     writes a 32K file in   2.41 seconds
     reads a 32K file in    1.43 seconds
```

My point is simple -- most benchmark programs have little relation to
"real world" problems. I would never use fwrite()/fread() nor 512 byte
blocks if I wanted to write or read a file in a hurry. (:-)

[]

A flame:

The version of hippo-C (Haba software) that I have for the ST
(although it has [fs]printf) lacks any form of [fs]scanf.
Does anyone out there know if this is just a problem with an early
release, or am I going to have to make myself a version that
runs under hippo-C?

An answer:

Hippo-C does not directly support a number of xbios calls. In addition,
Hippo-C passes everything as a 32 bit int, so a small amount of care
must be taken in writing routines that access xbios from 'C'.
(In particular it would not be easy to make a generic xbios(n,args...).)

So for example, to get the current screen resolution (Getrez() == xbios(4)),
the following piece of code is required...

```
     .global _Getrez
Getrez:  move.w   #4,-(sp)
     trap #14
     addq #2,sp
     rts
```

This routine will return the current screen resolution (0,1, or 2).

Not a particularly exciting routine, but what do you want - it's
free :-).

A Question:

Does anyone know where you can obtain a copy of the GEMDOS specification?
(I assume that you can get it for free if you get the developers kit,
but I would assume that it is available in some other way.)

I would be interested in hearing from other ST (and Hippo-C) users.
A small amount of communication might result in a large decrease in
frustration.

I got the idea that the "more powerful hardware" was just the larger
memory version of the ST. Any one out there know for sure?

In my years of experience, crashes are usually the fault of software,
not hardware. The exception is when a VERY immature hardware design is in use.

I use an okidata 82 (modified to 92 compatibility,) but due to some
ill thought-out madness from DRI, the only printer that can be used
with the desktop is an Epson *x-80. (The print device driver is hard
wired for Epson use, the code is unavailable, there is no current way
around it.)

If you don't want bit-mapped screen dumps, any of the standard micro
printers are just fine. The interface is slow however, and does not
operate in the background.

I'm posting my reply since others may be interested. I'm using a Panasonic 1091 printer with my Atari 520ST and am quite happy with it. Both text and graphics modes seem to work. [That is, the print-screen function does generate an image of the screen on the printer]. A very minor change in the STWriter configuration was required, something like ESC-H => ESC-T, to turn of superscript or subscript mode. Other than that, most things seem to work fine.

Also, an IBM-PC printer cable can be used to attach a parallel printer to the ST. That's easier than trying to figure out what works from the pinouts.

> Second, regarding which machine is best, obviously you & AT&T have
> differing opinions :-).

That's right. The ST is better for AT&T, since it needs a real operating system badly. The AMIGA doesn't need one since it already has one. There's no point in putting UNIX head-to-head with TRIPOS on the same machine. UNIX is the better O/S, but only by a factor of 2 or so. I hardly think most people would even notice the difference... after all, they seem to consider GEM/CPM nearly as good or better than Intuition, and it's not even in the running.

I am dieing for some technical information on programming the Atari ST.
Does anyboby know how to access the joystick ports. How about display
list interrupts or BitBlting? If anyone has some special knowlege or
perhaps pieces of the the ST memory map to contribute, I am sure, there
are many of us on the net who would appriciate it.

Thanks,

John

The GI AY-3-8910/12/13 series are not really music chips, they are noisemaker chips. That is, their purpose is to make noises, some of which may be musical in a general sort of way. They are not what you would pick for serious music work. They are, on the other hand, not bad for using sound in human interfacing -- they are vastly superior to a one-tone beeper! That is how they should be viewed: as a better and more useful replacement for the beeper, not as God's gift to computer music enthusiasts.

From: Jim Mayer <mayer>

I have a friend who is considering buying a 520ST as a word processing machine. To help him out, I went down to one of the local computer stores that is carrying the ST and checked one out a bit. The salesman was less than helpful however, and I have some questions:

1. Having looked at both the B/W and color monitors, my feeling is that anyone doing word processing should go with the B/W. As far as I can tell, if you have the color monitior you cannot use the 640x400 monocrome graphics mode at all! Is this true? If not, how does text look on a color monitor playing at being monocrome.

2. How big are the disks? I have heard several numbers banged about.

3. Is there a cut and paste word processor available or in the

works? I saw "ST-Writer" and "The Final Word", neither of which uses the cut and paste/mouse driven technology.

4. What is available in the way of printers? Does Atari make a printer? Can one use other printers?

4. The following strikes me as the "right" configuration for word processing (draft only):

    Computer
    2 disk drives
    monocrome monitor
    matrix printer

    Does that sound right to the ST owners out there?

Please reply by mail.

(*-*)

Now that I've got ST Writer, I've been trying to get my serial printer hooked up to my ST. So far I've been totally unsucessful. Printing from GEM doesn't seem to work at, no matter what permutations of ST and printer settings I try or what cable/pin cross matching I try.

The ST talks to my modem just fine however.

Now along comes ST Writer and lo, it spits stuff out the serial port. BUT,
it doesn't handshake with my SLOW printer. Aftera late night last night I
have found this: If I set the ST serial port to Xon,Xoff (which seems to
require a reboot(?)) the ST will stop when my printer sends Xoff, but fails
to restart when sent an Xon. I monitored the connection to verify this.
So, I tried hardware handshaking; same thing. As soon as the handshaking
signal CTS in this case comes along the ST stops and stays stopped. Further
more, in both cases the ST requires a reboot to bring it back to life.

Any suggestions ST gurus?

Could someone with the right technical info tell me which machine would
be capable of faster graphics? I need things like bus access interleaving,
raw graphics chip speed, and the complexity of basic graphics chip operations
taken into account.

Thanks,

Sean

> There is no such thing as a "visual copyright" per se.

This statement is not true. There is a separate form for filing what
the poster called a "visual copyright"; you file for text copyrights on
form TX, and for copyrights on audiovisual materials using a separate
form (I think it's called form AV). This latter is what is used to
copyright video game displays, etc.

All this is explained on an instruction sheet that comes with the copyright
forms which you get from the Library of Congress to file for copyrights.

Ref: Will Hom's message of the 25th, same subject (without ??).

The address for join ups and mail ins given in the Homgram caused my
Mailer Daemon to barf. Unknown Host, it said. The NIC data base showed
no such host on ARPA as "ucbugs.Berkeley.EDU", and the member list for
UCB-VAX had no Hom. I tried making the address "mail-atari-request%
ucbugs at UCB-VAX" instead. Haven't got a response, but I haven't got
a WTFO from the Daemon either.

Anybody else sort this one out?

> revisions, however I would not refer to them as buggy. The 68020 on
> the other hand...

(He must have left the ... because he didn't know the answer. Here it is:)

Motorola tells me that the bug list on the 68010 is zip, null,
zero -- and after working with it for years, I believe it. It's a
production chip.

After close to a year of work with 68020's, the last bug list I saw
(August) had three or four things, all minor, and I have every
confidence that these will be gone within a few months (if not
already). None of these affects user code or compilers.

Let me hear you say the same things about National's chips...after canceling
a whole product line because they didn't work.

PS: Not to run down National; they make great jellybean chips, and their
PALs are OK.

Of course, it was the Xerox Star, and not the Lisa or Mac, that first introduced this sort of interface to the commercial market. (The most noticeable difference between the Star and the Mac is the "wait" cursor being an hour glass on the Star and a wristwatch on the Mac.) As for this point-and-click becoming widely accepted, it is already in use on a large number of workstation-class machines, and a presentation on future directions offered by IBM in Rockville this past summer all but promised that IBM would move in this direction as well.

I need some tips on a good, complete C compiler (floating point)
for the 520ST. Quality and completeness of libraries and documentation
count heavily. Total GEM support desired.

Also, what does one get with the $321 Atari development package?

Several people sent messages to me regarding my inability to send mail to
join the mail-atari list. Most replies indicated they had no problem, but
several had similar problems. It seems that the csnet database of addresses
has no knowledge of ucbugs.Berkeley.EDU

In any case, the moderator of mail-atari, Will Hom, replied and suggested
trying either
ucbvax!ucbseymour!c50-2fl   OR
c50-2fl@uxbseymour.Berkeley.EDU   (sic. I assume he really means ucb not uxb)

I was unable again to send to either of these addresses. The message never
even gets queued up to be sent, and I get an unknown address message.

Will Hom, if you're reading, please add me to your list anyway. I can receive
mail from you even if I cannot send it to you.

Thanks.

> out with the 32332 already, when they haven't even come out with the 32132
> or the 32232 yet(Yes, these are actual scheduled components).

Last I heard, the 32232 was no longer a real part, and the 32132 is a minor
upgrade of the 32032. The plans got reshuffled a while ago: make sure you
have the up-to-date word. Yes, the 32332 is coming, and looks interesting.
Non-disclosure prevents me from saying more. (Except that they'd better

get the 32332 out fast without major bugs if they want any market share!)

> This argument is moot anyway for one reason. The 68020 is considerably faster
> because the original 68000 is very bus bound, while the 20 is much less so.

Let me see. You're saying that because the 68000 had no prefetch queue and
a 16-bit bus, and the 68020 fixes both of those problems, that the 68020 is
better than the National 32-bit chips? Does not compute: the National chips
have had prefetch queues all along, and the 32-bit ones have had a 32-bit
bus all along. The 68020 is a vast improvement on the 68000 in this regard,
but that is utterly irrelevant to comparing it against the 32000s.

> ... Also, a memory cycle
> on the NS series and the 68000 is 4 cycles, as opposed to the twenty, which is
> 3 for main memory, and 2 for the 256 byte queue.

Let me know if you can find a 68020 system that really does a main-memory
fetch in 3 cycles. It's extremely difficult to build low-cost main memory
that can run that fast (although caches can help). Don't forget to add the
delay for memory management.

The "Desk-top" represents only a small fraction of both systems. DRI
produced a "GKS/VDI" interface even before the Mac was released.
Agreed, Apple should recieve something for their contribution, but are
lawsuits the best way to get it?

To give DRI the benefit of the doubt, assume that DRI didn't know that
they were copying a protected "functionality". Assume that they believed
they were makeing sufficient changes to avoid a lawsuit. Apple sends a
notice saying they want $200/copy (anybody know the figure?). DRI only

charges $50/copy, and offers $2/copy. Apple sues.

> George Hart, Computer X Canada Ltd.

My backround is in performing arts management, music, dance, theater.
There are an incredible number of parellels. Around the turn of the
century, music composers and publishers saw the phonograph and radio as
a threat to profitability. There are "subroutines" in music such as
"12 bar boogie" which were difficult to protect with the usual
copyright laws, because different melodies could be played over the
basic accompanyment. In fact, there are over 200 "Jazz Constructs"
which have the same basic protection problems as software.

Rather than spend small fortunes in the courts, the American Society of
Composers Arrangers and Publishers (ASCAP) was formed. When radio and
international broadcasting created a similar threat to "R&D", Broadcast
Music International (BMI) was formed. These organizations serve as
"Central Clearing Houses" for royalty distribution. In restaurants,
disco's, and theaters (or wherever music is played commercially), a
basic monthly fee is paid directly to ASCAP or BMI, usually around $250
to $500 per month. When recorded media is sold, the publisher pays
ASCAP or BMI. Both organizations co-operate with each other so the
author gets royalties either way. The subscriber keeps a log of what
he plays and sends that in with his payment. Each publisher, composer,
and arranger recieves royalties.

In this way, if an "easy listening" arrangement is made from a former
"Top 40" seller, the Arranger, Composer, and Publisher of both the
original and the easy listening version get royalties, even though
the courts would probably not enforce a "Copyright Suit".

A publisher/composer has "exclusive use" to the work for a certain
period of time, though he still pays a standard "subroutine royalty"
in case the "new release" uses one of them. Unpaid royalties go
to a pension fund.

The formula for royalty distribution is quite complex, even the
payment schedule is a little wierd, but it does provide a very
profitable and democratic means of rewarding creative effort.

Similar arrangements have been made by the video cassette and
film producers/publishers. Even the unions are involved in this
distribution process. Notice that ASCAP circumvented the need
for unionization of music writers.

One of the reasons that the current Copyright, Trademark, and
Patent laws are still so unclear for the software industry
is that other industries have chosen other avenues which
are more cost/effective that the courts.

There exists an organization, the Software Publishers Association, which
appears to be investigating a similar role in the software arena.

Currently, there are a few companies which are reluctant to participate, but I would encourage BBS sysops, "Share-ware" authors, even "Public Domain" authors to get involved in this or any similar efforts taking place. Other organizations to "lobby" might be ADAPSO, IEEE, or ACM.

The alternative is to depend on "Trade Secrets" and a fickle court system and a lot of heavy paranoia along with "copy protection" systems that can do anything from make an otherwise useful program useless to wiping out entire hard disk drive file systems.

This is Rex Ballard, I've been moved to

I suppose I also find it interesting that no one has responded to your request for benchmarks. Could it be that the speed at which lines can be drawn on the screen isn't important. Doesn't everybody buy a computer to access a 32K file as fast as possible? Hmm, maybe people really buy these machines (and their software) to acomplish a task, to get their work done, or just plain enjoyment. Definitely a radical concept. This will all come clear to you once there is software available for your machine too.

(*-*)

Has any of you out there with a developers package or the Habba "c" system
tried to port XLISP or perhaps PC-Hack to the ST? I'm waiting for the
British port of Lattice "C" (by Christmas maybe?) but I'd be happy to trade
some PD stuff for either of these programs if someone has ported them.

I have ST Writer, Neo and a few more demos.

(*-*)

Yesterday my local computer store (Von's Computers) recieved a copy of Final
Word(tm) by Mark of the Unicorn for the Atari 520ST. It appears to be the
same version they offer for the IBM-PC and other MSDOS machines. It comes
with both the editor and formatter, as well as a 1.5 inch thick manual.
List price is $150.

And who says the ST is devoid of software?

I sent the message below to Sean Casey, in reply to his most recent posting concerning the mailbounce issue. I forgot to Cc: it to info-atari, and am doing so now, so that others can read it, as the information contained therein is of general interest. Please note: I am not anyone official here at MIT, but I have spoken with several highly placed people here, all of whom gave me the same information, which you see below. Some of it may sound drastic, but according to these (very reliable) sources, this is the way things are. If you have information to the contrary, please send me mail.

To those who requested the pmd program described in my last posting, it still has some bugs in it, but I should be able to send it out soon. Please be patient. At present it only has been tested on vaxen running BSD 4.2 and 4.3 unix.
--jh--

Since you received and acknowledged my posting, I can only assume that you didn't understand my main point. I'll restate:

The only individual you can possibly pin any blame on is Mark Crispin, our old moderator, for not turning off the info-atari mailing list when he ceased to be moderator.

This is because of the nature of arpa mailing lists. Auto-remail programs work fine, until someone changes his mailing address without telling anyone. This is why there is a moderator. This is in our case the ONLY reason we have a moderator, since Mark never changed anything posted to the list. Now he is gone, and the reason to have moderators in the first place becomes evident: some mailing addresses changed, and the list doesn't know about the changes. The result is that the mail demons at the machines containing the now-nonexistent addresses must return the mail to the sender, notifying him/her that he had the wrong address. Furthermore, it must do so as soon as the attempt to send is unsuccessful, and try again, because often software or hardware is broken, and that, rather than bad addresses is why the message went undelivered. They compromise at two retries, one per day, which is why you get three mailbounce messages. If you complain to anyone but the list (and by now it's getting REALLY boring, after all it's our fault no more than yours), think what will happen:

If you send to the postmaster at score (your only serious choice), he or she will kill the list unless he is AMAZINGLY tolerent and removes the nonexistent addresses himself. He is required to fix the problem.

If you send to the postmaster at the machine(s) with the nonexistent addresses, he or she will look for the source of the problem, find that the problem is our lack of a moderator, and then send mail to the postmaster at score (see above). I am surprised that the machines with the nonexistent addresses have not already had us shut down, as we bounce 10-15 messages each day from their machines.

If you send them to the nonexistent address, they bounce, each message becomming three, each of which you send back, and you get nine messages, then 27, 81,...,3^n. Where n is the number of days it takes for the people at the poor, unsuspecting site to get mad. They, after all, don't know what is going on, except that a lot of mail is coming at them and going to an address that has been dead for a while, that all of it was originally to info-atari, and that a geometrically increasing amount is from you. They may not even have known that info-atari exists before they received enough mail to cause problems (believe me, for any normal arpa site, that's a LOT of mail -- we (MIT) don't crash until we get 4000 messages simultaneously, and I doubt the usenet can send at that speed. It sure would hurt your phone bill, though). Their only recourse is: 1. Send mail to you asking you to stop bombarding them with mail. 2. Send mail to your postmaster telling him to stomp on you and the flagrant violation of arpa rules (true, arpa has no jurisdiction, but it does have priviledges they can revoke. See below). 3. If nothing changes (doubtful, as your postmaster will still want arpa access), cut off the uucp/arpa gateway. 4. To kill info-atari, which the postmaster at score will do (indeed, is required to do) as soon as anyone complains to him officially about any of the problems talked about, because without a moderator we are basically "illegal" (groups such as this are "illegal" even with moderators because they "waste" DoD resources, (and wine-tasters' being blown away BY AN ACT OF CONGRESS WHICH SHOULD HAVE KILLED ALL ARPA MAILING LISTS attests to this)).

That is the way things are, according to the local network expert (professional employee of the Massachusetts Institute of Technology, not a random hacker). If there is trouble, info-atari goes away, and uucp/arpa access and your account are in grave danger of a severe stomping-upon. If there is continued trouble, mailing lists in general go away. Remember, arpa is a DoD construction, and, as the backbone of the internet, what happens here affects a lot of people. The sum spent on the net each year by the DoD is enormous, and every year generals and other military people whose programs had funding cut complain about the cost of supporting conversation between college students and professors being unwarranted as part of a military budget. We exist at their indulgence, and if we behave badly, the damage in revoked priviledges will be enormous.

True, as a uucp node, you have a legitimate gripe. If the problem becomes unbearable, please take the comparatively mild solution of complaining to postmaster@score. Then anyone who REALLY NEEDS this list is free to moderate it him- or herself.

DATE: October 31, 1985
TO: Atari Deep Blue C users
FROM: Bill Swortwood
SUBJECT: Lack of Scanf

I have been working on my 'C' programming and have found that one of the most common feature of 'C', scanf , is not part of the I/O library. Before I undertake trying to re-invent the wheel, I want to plead to anyone out there that has had the same problem and has already written the source code

to send a copy
here for us novices who are going through extreme pains to just learn the language.

Also, for the user who wants a copy of the Technical
Reference for the Atari as well as the book 'Your Atari', I have some suggestions as to where to obtain these.

For the Technical Reference, try :

B & C Computervisions
3283 Kifer Rd.
Santa Clara, Ca. 95051
(408) 245-2680

or

San Jose Computer
1844 Almaden Rd.
San Jose, Ca. 95125
(408) 723-2025

There is also a new SAMS Technical Reference for the 400/800 at Computer Literacy in Sunnyvale Ca. (which, mind you, has one of the few large selections of Just computer related books on the planet).

bye for now,

Bill Swortwood

Disclaimer: Amdahl Corporation has no connection with my personal PC ownership or use thereof, they just make very, very fast and reliable mainframes and pay me to help continue the effort to do so.

Summary: PC?

In article <2800013@ccvaxa> preece@ccvaxa.UUCP writes:
>
>> This article reminds me of those who said in 1980 that IBM's entry into
>> the personal computer field would "legitimize" the industry. (Remember
>> when "PC" meant "a personal computer", not "an IBM-compatible 16-bit

     No, I don't remember when "PC" meant "a personal computer" in any generic sense. And I doubt if you do either. The only PC's that existed before IBM were "Pocket Computers". IBM coined the term personal computer.

>Would you claim that the micro industry would be be better off if
>IBM had not come in? Think for a moment of all those builders of
>IBM clones. IBM has very nutritious coattails. Apple may or
>may not have been wise in suing DRI, but they would almost certainly
>sell more Macs if IBM made one just like it than they do now. [Note
>to flamers: it's just my guess against yours, but I don't mind if

     I think it's fair to say that if it wasn't for IBM we'd be in a worse position today. We'd be stuck with CP/M in all it's forms rather than MS-DOS. At least it can be said that MS-DOS is generally better (in it's version 2 form) than CP/M86. Still, a lot more 'other' systems such as QNX or OS-9 or Pick or whatever might have grown more rapidly yielding a much better array of systems for the future. As such I may be wrong.

                                    Cheers! -- Jim O.

Summary:

line for bit bucket

I tried an olympia model np?? printer on the st and tried to screen dump. It sent one valid line of the screen and then three lines of garbage ,one valid three garbage .... So I went into the printer designation menu and set the printer resolution to the lower setting and then tried to screen dump again. Much to my surprise got a very nice screen dump complete with the bee. Does this mean that the Olympia is mx-80 compatable or that screen dumps work with more than just epson's ? I suspect that any mx-80 workalike will do screen dumps.

note I tried to print with a non-functional printer and ended up hung where the only way out was to reboot. read: could be trouble!

This was written from memory and could contain inaccuracies.

Bill

Excuse me, but I certainly hope you meant to put a :) after that sentence.
If you didn't, I'm sure that you never heard of an Apple personal computer
or a Radio Shack personal computer. Both were introduced years before
IBM entered the market. Neither of these was the first personal computer
by a long shot. The term "personal computer" has been around a lot
long than IBM's PC has. IBM's use of the term PC is merely a marketing
ploy designed to make people think of their product first when the terms
PC or personal computer are used.

>600s and 1200s shouldn't feel excluded.)

As much as I agree with the problem, I have to disagree with the suggestion.
The 800 (et al) are as dead as lots of other machines with loyal followings,
and the need for a newsgroup for new technical data, rumors, O.S. arguments,

etc. is just not there.

Maybe we can all afford to upgrade some day ...

Ok - so we ran it on an Atari 520ST ... 1092 Dhrystones/sec. This is,
of course, independent of graphic mode, but if you wave the mouse about
it slows down a bit.

Nigel Roles

P.S. The benchmark is wrong. malloc() should be declared as char *.

Oh, come on. The term was nothing like as ubiquitous as it is now,
but both the term "personal computer" and the initialism "PC" were
in common use (among the relatively small number of people interested
in such things) well before the IBM PC. One of the complaints about
the IBM was that they had co-opted a common and useful term as their
trademark.

I have accidentally posted some ST source code to this group. I meant to post it to net.sources. Sorry.
I had received a number of requests for this program. Sorry it took so long for me to post it. I also have a terminal program that allows unlimited screen save to either the printer or a disk file. It was created with the Hippo C compiler. I have been using it at 1200 baud with various company computers with no problem. If I receive enough requests (1) I'll post it to net.sources.

Well there was just today a posting from someone who requested data on the
600. I'm not loyal to the 800 at all. I gave it to my mother because
she wanted to learn something about computers. (Flames about parent-abuse
to /dev/null, please. It was her idea.)

Anyway if this group only had ST postings, it should be renamed to
reflect this.

          December 1985 ANTIC magazine TOC
          Theme: Annual Shoppers Guide

page article

10   ANTIC ONLINE
          Some information on the Worldwide Users Network.
12   COMMUNICATIONS: BBS CRASHBUSTERS
          Bulletin board sysops can now foil destructive "crashers"
          with this machine language USR call. It quickly strips all
          non-standard ATASCII characters from input strings.
14   VIDEO STAR ATARI

A review of several programs of interest to those using their Atari for graphics; including 'Computereyes', 'Rambrandt' and 'Graphic Shop'. (Last two available through ANTIC catalog)

20 NEW LUCASFILM GAMES
A review of 'Eidolon' and 'Koronis Rift', including an interview with some of the developers.

26 DISKIO PLUS
This spectacular update of the original DISKIO disk operation utility provides instant, one-dot keystroke commands for nearly all DOS functions, an alphabetized disk directory, single key macros and much more. All without touching your resident program.

30 SHOPPERS GUIDE
A review of latest Hardware and Software available for the 8-bit Atari machines.

46 ST SHOPPERS GUIDE
Save as above, except for the ST computers.

51 4xFORTH
A look at the first serious language for the ST users.

57 INTRODUCING 520ST ASSEMBLY LANGUAGE
A Motorola 68000 tutorial.

60 ST LOGO EXPLORATION
A simple program to look at uncharted memory locations.

69 ASSEMBLY LANGUAGE: BUILD YOUR OWN EPROM BURNER
With a little over $30 in parts, some careful wiring, and this assembly language program, you can build your own EPROM burner. Requires construction.

76 PROBURNER
A review of what ANTIC calls the best EPROM burner on the market.

79 GAME OF THE MONTH: BOX-IN
You'll find an intriguing combination of arcade action and strategy challenge in this simple but highly involved game from the author of 'Biffdrop' and other ANTIC hits.

83 SOFTWARE LIBRARY
All the type-in programs are located together here.

98 U.K. GETS ANTIC CATALOG
ANTIC software is now going to be available locally for Atari lovers in the UK, Canada, Australia, New Zealand, Germany and Latin America.

Comments: Antic reports that DataSoft has shut its doors. You may be able to pick up their 'Micro-painter' pretty cheap, watch ads for sales. Koala Technologies has reversed their decision and will support the Atari users with their Koalapad after all. This means that you probably missed all the good deals if you haven't bought one yet. I had seen them as low as $29.95. 'VIP PROFESSIONAL' for the ST is now being advertized for $179.95. It was being pre-sold for $99.95 last month. Several new (and I assume small) companies are advertizing software for the ST computers. Enjoy...

Hi, I just bought the ST and I need some help.

First, where can I get some documentation on GEMDOS.
This seems to be very critical if you want to use the
power and capabilities of the ST. I saw this question
posted earlier to the net but I saw no response.

Second, someone asked a while back if "scanf" was
left out of HIPPO-C (Habba). I would like to find
out if this is true for the current versions being
sold. I bought it with my ST but I have to return
it because I get a bad disk. I plan to program in
C and I would like to be able to use all of its
capabilites (plus the GEM functions).

Please, if questions like these are posted, please
post the answer to the net also. There have been
many good questions posted but I have seen very few
(or no) answers.

You can flame me if you want because I am asking for
responses on the net but it is better than constantly
seeing "DRI agrees to change GEM" articles. I want to
see more relevant information about ST being exchanged.

"the need for a newsgroup for new technical data, rumors, O.S.
arguments,
etc. is just not there."

I have to disagree with *that*. It was on this newsgroup that I found out about the $4.95 1200XL keyboard from Radio Shack for my Atari 400 *and* the pinouts to hook the thing up (thanks, by the way to the person who provided that - I tried to reply to you personally, but our brain-damaged mailer refuses to parse addresses > 65 chars.).

Now I'm looking for information on how to upgrade my memory to 48K. I've heard it involves some 64K chips and cutting a few traces, but I haven't been able to get any details (I also browsed around inthe archives).

Also, does anyone have an Indus drive they'd like to part with? The lowest price (new) I've found recently is $200, from a mail-order place in New York.

- Michel

>The 800 (et al) are as dead as lots of other machines with loyal followings,
>and the need for a newsgroup for new technical data, rumors, O.S. arguments,
>etc. is just not there.
>
>Maybe we can all afford to upgrade some day ...

   As much as I agree with the disagreement with the suggestion, I have to disagree with the opinion expressed by Mr. Gordon. While I don't believe there is a need for a new newsgroup, writing off the machines upon which the Amiga (yes, Amiga) is based due to some sort of computer snobbery is ridiculous. Those "dead" machines not only exist in the homes and offices of literally tens of thousands of people, but continue to have new software produced for them. Add to that the fact that the recent dumping of 'em on the market at extremely low prices makes for a lot of people with a need for *old* technical data, and those "dead" machines rise miraculously from the grave (not unlike a grade B horror flick :-).
   On the other hand, if you think gigabytes of Amiga vs ST flamage is a necessary thing, perhaps a separate ST newsgroup *would* be a good idea. We'll call it "/dev/null".

 - Joel Plutchak
   {allegra,ihnp4,seismo}!uwvax!uwmacc!oyster

Can you say "opinion"? I *knew* you could!

P.S. Have any of you necrophiliac 8-bit Atari users seen the latest Lucasfilms software (Eidolon?) yet? Is it worth owning?

I'm looking for anyone who's had experience interfacing a hard disk (not
Atari's or Haba's) to an ST. I've been offered a relatively cheap 10M disk,
but will have to buy a controller and power supply for it. Is this going to
be difficult? Also, am I really getting a good deal on the disk? I can

pick it up for $150 (new, but I don't know the manufacturer). How much can
I expect to pay for a controller and powersupply? Does the hard disk
interface in the ST make this easy?

Your comments and suggestions are greatly appreciated!

=-=
No problem is so formidable that you can't just walk away from it.

I hope to shout! How about the PDP-1, PDP-8, & PDP-11 by Digital Equipment
Corp. The PDP stood for "Personal Data Processor" and was probably the first

standalone interactive computer that didn't require massive resources needed
to support a mainframe. I believe the first dates to the early 60's.

1) The term "personal computer" has been around since at least the early
70's.
2) A PDP-n from DEC is a "Programmed Data Processor", not a "Personal Data
Processor." The name came about because DEC was selling to organizations
which had managerial problems in buying "computers" (which were multi-million
dollar machines even though DEC's machines weren't) but could easily purchase a
"programmed data processor."

     I agree with the original posting. I too have an Atari computer,
but have no intention of buying the new ST machine. And I strongly
disagree with the last statement. The ST machines are NOT repeat NOT
an upgrade from the 400/800/1200XL/600XL/800XL line of computers. They
are not compatable, and there for are not an upgrade. When we upgrade
the computers here, we don`t have to throw out all of the software that
we have. In the worst case, it must be recompiled. That is an upgrade.
If I "upgraded" to the ST line, I would have to throw out over 300 disks
of software. There is no way that I am going to do that to support Jack
Traimel and his personal dreams of glory.

     Sorry about the flame, but I couldn't help myself.

With regards to 'scanf' and Hippo C; it isn't included. If you look at the libraries included with the compiler, you can see what Kernighan and Richie functions were included. Hippo C does support most of the GEMDOS, AES (what's that mean?) and VDI (Virtual Device Interface) calls. However the documentation of these calls is poor. Also, the executable file is extremely large compared to source code. What I mean is, if you compile, assemble, and load a 2 or 3 line program, the executable file is about 10K in size!!! I'm not sure why, but I think that at load time, all of the libraris are loaded whether they are needed or not; not very efficient but safe.
I've been struggling to make sense out of the AES and VDI calls (since I don't have a developer's package) for about a month now. Since Atari isn't cooperating (unless you have $300.00), maybe us poor folk ought to document the AES and VDI calls on the net (if and when we discover their usage).
Maybe if we post incorrect AES and VDI documentation, someone with a developer's package will correct us (I hope).

You may not remember when the term 'personal computer' meant just that
in any generic sense, but you are in a minority of one. If you still
don't believe me, just look through any old issue of magazines such as
'Byte' in the pre-IBM-PC days, when men were men. I distinctly remember
thinking at the time when IBM announced their 'PC' that it was a shame
they called it that (although a clever marketing move). They have
forever tainted a perfectly good word, much the same as the media has
ruined the wonderful word 'hacker'.

I stand corrected as to "programmed" vs. "personal".
May i offer a suggestion that we at least mitigate some of the effect of
itty bitty machine's usurpation of the term PC by referring in our written
correspondence to the generic as "pc"?   der

Some information on modems that might be of interest to all:

The latest issue of the newsletter from CompuClub lists the Communicator II kit, which includes the 835 Modem and software, for $25.95 while the supply lasts. I believe that kit also included the CompuServe starter kit with 5 hours of free time. If so, you would get the 835 modem for free!

On October 13, Neil Harris, managing publisher of 'Atari Explorer' gave a talk at the meeting of the Northern Virginia Atari Users Group (no I wasn't there), and he said that the XM-301 modem is shipping from Atari. The software was written by Russ Wetmore and so it is very similar to HomeTerm from Batteries Included. The list price is $49.95, but it only includes one hour of free time on CompuServe. It's advantages are that it is very small and has no separate power supply. He also said that Atari is not currently working on a 1200 bps modem for the 8-bit machines.

Hope this helps...

<This was originally E-mailed out as a response to a posting by duts!bhs00.
 However, since it got returned to me, and might be of interest to others
 here, I'm taking the liberty of posting it.>

   Thanks for the info on where to find the Atari Technical Users Notes.

   As for your Deep Blue C problems... well, I recently purchased Deep Blue C, and frankly, it's lacking in several respects. First and foremost, it is *not* a true compiler. It "compiles" into pseudo-code, which is subsequently translated for execution at runtime. My admittedly non-exhaustive testing has shown that it's maybe 20% faster than interpreted Basic, and the generated command files take up a lot more disk space (I don't have the figures with me). Another large problem (why the .COM files are so large) is that the linker doesn't use libraries; if a file is listed in the .LNK file, the entire thing gets thrown in, even if you're only using one of the functions.
   As chairman of the local Atari User's Group languages SIG, I have just embarked upon the odyssey of attempting to write a "true" Small-C compiler, complete with relocating linker featuring library management. Now, it may be that I come to the conclusion the J. H. Palevich did (i.e. it's not possible, given diskspace and memory constraints), but I'll learn a lot trying. If you have any suggestions, comments, etc., let me know.

I have noticed an awful lot of questions on the net regarding
the poor documentation provided with the Hippo-C compiler. If you post
specific questions regarding any undocumented VDI, AES, and XBIOS calls

I will try and answer them as best I can. Right now, I am putting
together a list of XBIOS calls (such as Getrez, Setscreen, and Giaccess)
and their corresponding "xbios()" calls, and will post this info to
the net as soon as I am finished.

all right, i admit i was probably wrong since i was relying on old information
but i from what i hear, nat semi is still having problems with their components
and the only thing of theirs that i would consider using is a 32081 fpu, and
this is only till motorola comes out with the 68881

that was exactly what i was saying, that the nat semi chips show no great
improvement in speed as we up to bigger bus widths, while the 020 is a lot
faster than the 000 because of the inclusion of these new features, also, im not
sure, but i think the 020 also includes pipelining while the 000 didn't(is
this right?)

>   Henry Spencer @ U of Toronto Zoology
>   {allegra,ihnp4,linus,decvax}!utzoo!henry

about that last comment, the 020 is capable of doing main memory fetch in 3
cycles, and a queue fetch in 2 cycles. the 80286 i have heard can do a main
memory fetch even faster, but that doesn't mean it will when implemented.
NOW, why should i include a delay for memory management? I mean, why should
i have memory management? we're talking a single user system here with maybe
a few small background tasks. I dont understand this idea of strapping me
with memory management when i do not want to use unix or anything similar
to it in complexity.
the simpler the os, the faster the system. and i have used att 3b2 unix
 personal computers and they are slow, even though there are provsions
 for up to four users in them. i believe this is because of the os(unix)

 ah, well, i am getting philosophical here, so

I currently own an 800XL I bought last year for cheap as a game/teaching
software machine for myself and my family. I currently WANT to own
an ST, because I feel it will be a viable machine for the future. Yes,
the 8-bit series seems to be getting phased out for the ST (and TT?),
but I STILL WANT to see articles on both; the 8-bit for now, the
ST for the future. The level of traffic in this group is not that
huge; is it really that burdensome for people only interested in one
or the other machine to skip past (to them) irrelevant articles?

Nobody will notice. The best idea I've seen is from Hugh Daniel, who
calls them "IBM Feces".

Can we go back to talking about atari computers?

To the best of my recollection, DEC didn't use the word personal in
conjuction with computer until the late 70's: they certainly weren't
using it in the 60's. I qoute from my 1963 edition of the DEC PDP1
handbook:

  PDP stands for *Programmed Data Processor* and is a trademark
  of Digital Equipment Corporation.

The same quote appears in my July, 1969 edition of DEC's
  Introduction to Programming
    PDP-8 Family Computers
and my 1970 edition of DEC's
  Small Computer Handbook

I can find no expansion of the PDP acronym in any DEC manual with
a publication data later than 1970.

Please forgive me if this should be routed to net.micro.atarist, but I don't know if there is one:

I need a summary of the features of the 520ST. My brother-in-law saw a "real good deal" on an ibm-compatible (a Zenith Z-148) with a printer for $1800. I'd sure rather see him get a more capable, up-to-date machine like the Atari (btw, the Amiga is just out of his price range).

If you can summarize, please send directly to me. Thanks in advance.

In the latest Infoworld (14 Oct), Dvorak says he thinks the ST will win out over the Amiga. He also talks about the rumored Nat'l Semi 32000-based machines being worked up at Atari; he says that Nat'l wants the business so bad that their people are taking an active hand in getting the 'TT' series designed ('ST' for Sixteen/Thirty-two, referring to the 68000's bus/internal widths vs. Thirty-two^2 for Nat'l part).

Mention is also made of the AMIE sound chip upgrade and a possible 256-color graphics chip upgrade. Couple this with the AT&T deal alluded to in the Washington Post (see the followup to the item I dragged over from net.amiga), and Atari looks real good vs. Commodore.

Now, how soon will this stuff hit the shelves?!?!

Question for ST developers:

Does the ST allow you to set the interrupt vectors, and can the ST
generate timed or periodic interrupts?

Any other comments about ST internals would be welcomed as well.

I too bought one, and promptly set about in search of my Dec '82 Creative Computing, from which the following matrix is derived. Note that this is the original 400 keyboard circuits; I haven't finished tracing the 1200 keyboard yet to figure which pins go where.

wire #	1	2	3	4	5	6	7	8
9	brk			ctl			both shiftkeys in parallel	
10	7	6	U	Y			N	
11					J	H	spc	
12	8	5	I	T	K	G	M	B
13	9	4	O	R	L	F	,	V
14	0	3	P	E	;	D	.	C
15	<	2	-	W	+	S	/	X
16	>	1	=	Q	*	A	atr	Z
17	bs	esc	ret	tab		cap		

also, there is another set for the system keys

	18	19	20	21
22	reset	opt	selec	start

The article implies that these numbers refer to those of the wiring trunk at the 400's membrane end. I haven't figured out yet the values for the extra pf keys, but it's a pretty good bet that they sit in the blanks for rows 10 and 11.

Once again, I might remind the net that Xerox can't sue Apple for anything
because Apple licensed the desktop/Small Talk stuff from them and paid
money for it.

In this much I think I agree. I've said before on other systems that memory resident utilities aren't always a good idea. It impinges on user memory, whereas generally it's not critical to maximize their speed (sorry, I meant to say 'they impinge'). Most of my day is taken up using terminal emulators and word processing. On my system directory calls take a fair bit of time. It's really not that important.

If you want to razz somebody on this point you can say to them "hey man, don't you ever do any *work* with your computer, what do you do just copy and delete files all day?" -- then duck fast.

>
>And why wasn't net.micro.amiga included in the distribution of this message?

>Anyway... you can regain your respect for AMIGAdos. It's not UNIX by any means,
>but it is certainly an improvement over Crummy-Dos, Trash-Dos, Messy-Dos, or
>any of the other little computer "operating systems".

But I have to disagree with this. Have you ever worked on the computers you've just slighted? I don't like Commodore's DOS (I assume

that's the first one you meant), but the Shack's DOS is quite good. In
fact, probably better than the Amiga DOS from what I've heard so far.
I'll reserve judgement. MS-DOS isn't that bad either. It could have
been better, but it's development was originally an outgrowth of CP/M.

     As for other 'little computer "operating systems"', ahem, like
Unix maybe? Or OS-9? I have heard *nothing* which indicates *any*
superiority of AMIGAdos as such over OS-9 in *any* way. But, mainly
remember that even Unix *started* as a small OS. It just grew a lot.

I personally do not want to see Apple get a patent for there (Xerox) user
friendly operating system. What we need in the computer world is more
user friendly operating systems, not some small upstart dominating the
whole concept of user friendly machines. Granting a patent will set
computer friendliness back too many years.

I am posting this question for a friend who just got an ST and wishes to use
it with his VolksModem to work on the VAX here.

What terminal programs are available now? What do they do? I am interested
in a good VT-100 emulator. We tried the VT-52 DA, but it didn't seem to use
the cursor keys, let alone the keypad, which seems a waste.

Please mail responses to me; if there are enough replies I will post them.
Thanks in advance.

Keywords: Atari keyboards; read on bold adventurer
Summary: and now the pin correspondence

Well, I sat up and figured out the pin correspondences so you wouldn't have to. It seems Atari saved space (and wire) by moving those chips to the keyboard, and so now, here is are the translations from the new wiring to the old. Old pin numbers refer to my previous posting.

	new pin #	old posting pin #	
IC #1	14	1	
	1	2	
	2	3	
	15	4	
	4	5	
	13	6	
	12	7	
	5	8	
ribbon pin	#1	9	
IC #2	1	10	
	2	11	
	15	12	
	4	13	
	5	14	
	14	15	
	13	16	
	12	17	
ribbon pins	10	18	reset
	11	19	option
	12	20	select
	13	21	start
	14	22	(common to above)

I believe the matrix is correct, since I've tried at least two intersections for each wire number. Beset by a flakey meter, it took me nearly 20 minutes to confirm my suspicion that old pin 9 was connected to ribbon pin 1.
BTW, ic#1 refers to the one on the left, between the m and comma keys, and just in case somebody doesn't have the red stripe, ribbon numbers are numbered from the spacebar side to the edge.

Get those 400's doing something. NOW!

According to a friend close to the industry (quote, unquote), GEM was
designed by a formed Apple employee. When he joined Apple he executed a
standard post-employment agreement. This agreement prohibited him from
implementing look-alike products for some period after he left Apple.

For some reason he didn't inform DR of this agreement. Perhaps he forgot,
perhaps he didn't understand it, perhaps .... In any case, DR was in a
defenseless position and had to accept any quasi-reasonable terms
that Apple offered.

OK, can anybody provide further information?

Sincerely,

[]

I finally got a chance to browse through the ST developer's package. I don't think I saw the full-blown package, missing were docs to "mince", the new editor "micro-emacs", "kermit" (but there are hundreds of pages of docs for "kermit"). Also missing (that I noticed) was the DDT debugger (or whatever name they gave it). Can anyone tell me if I was really missing that stuff or you didn't see it either?

My questions, having used it for a while and read the documentation, is the following:

1) the documentation really points to the OS being based on CP/M68k, there is no mention ever made of MS-DOS (except for when they say that GEM was originally meant for the PC, but can be ported to other architectures). Then why do people here say that it is not a CP/M68k derivative? The compiler-assembler-linker produce CP/M68k executable files, and then there is a utility which converts to GEM applications. Unless there is some other info that I am missing, this seems to say quite convincingly that the OS on the ST comes straight from CP/M68k.

2) Using this system I tried to compile a simple program, it worked fine and fast enough (the floppies on this system are really fast!!), then it assembled (a bit slower, but still fast compared to all compilers I've seen on the Mac with the possible exception of Rascal). Then:

HOW DO YOU INVOKE THE LINKER ON A FILE "hello.o" which uses the documented library function "printf()" and nothing else?

this is what I tried : I installed "link68" as a "tos application with arguments", which means that the program asks me for arguments. Then I called it up giving it as arguments "hello.o". It told me (quite expectably) that "_printf() was unresolved". Then I tried giving it

other files I found on the disk together with "hello.o", for example "gems.o", "acstart.o", "gemlib".... but in those cases it returned to the desktop before I could even see the error message.

    There are a couple of batch files " linka.bat" and "linkb.bat", but both of them want as input file "file.68k" rather than "file.o". In such a case, my question boils down to "how do I get a 'file.68k' rather than a 'file.o' file??????????????".

    Sorry for the long and verbose questions. One last thing is: does this system really not have floats and doubles? The documentation says NO, but then lists the function calls "atof" etc.... Other than this confusion of mine, I think the package is nice to work with and there are a lot of utilities.

     Thank you very much,
                        Mark Galassi

    Good point! However, I like the object-orientation of the STAR Desktop and
    wish that SOMEONE would make it available in a consumer-affordable form,
    since Xerox apparently refuses to do so.

How about $5000 plus a tad more for the software? Xerox Office Systems announced a new 6085 machine a short while ago (month or two). Its a complete redesign of the (previous expensive) hardware that was needed to run Star. There's also a new incarnation of the Star software called

"Viewpoint" (which is even better I'm told, but I never used Star and thus don't have an opinion).

It implements (now) more or less what the Mac office promised. I've seen and used it a few times. The hardware is winning too (but I'm biased). It has a microprogrammable CPU, NOT an Intel series chip, although a slave 80186 acts as an IO processor.

I can dig up and mail an address for more information to anyone who's interested.

(ron)
PS- Although I DO work for Xerox (but in a different division) these opinions are honestly my own and hopefully won't be construed as some kind of commercial nonsense. I personally like getting information about products directly from the people who worked on them (but I did not work on the 6085 or Viewpoint).

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

the story i heard was that Amiga was paying EA to develope S/W, hence the bias on EA's part. Amiga's philosophy seems to be if you spend million on advertising you can sell anything; Atari seems to believe if you save the customer money you can sell anything. i don't know about you but i'll stick with Atari.

Joe,
I will soon have a 256K upgrade for the 800XL that will make it look like
a 130XE+128K for $99.95. They will be ready in a couple of weeks.

Somebody correct me if I am wrong, but doesn't XEROX sell the AT&T PC
running GEM as their low end office automation machine? If true
apparently XEROX doesn't give much validity to Apple's copyrights,
patents, etc.

Apples versus oranges. Visicalc's claim might be better (depends on a
lot of things: whether they tried to protect it (by registration or
copyright notice), whether it was protectable (it looks a lot like a
non-automated spreadsheet), how close the clones were (same keystrokes?
same interface actions?)) or it might not. The important question
isn't whether they had a better claim but whether they pursued it.

Copyrights are not enforced by any agency, they're enforced by the holder. I think Apple would have been a lot better off NOT pursuing the GEM similarities (suppose they had told DRI, "You can go ahead as-is, but you have to say 'Desktop interface copyright Apple Computers.' at the bottom of the screen"?).

If we had a real standard for a visual interface we would all be a lot better off. There would be a big market in porting it to other environments. It would gain in respectability. Instead everybody has to try to be enough different that they don't look, at a casual glance, like a Mac (or, presumably, anybody else). That's a waste of effort. Differentiate by features, not by feel.

Apple also ignores another possibility. DRI may spend some time thinking about the interface and come up with enough improvement that in a couple of years Apple has to license features from DRI. After all, DRI is selling across markets and is much better positioned to become a standard. Consider the relative number of PC-clones and of Macintoshes. One would think that Apple's best shot at penetrating the business market might have been to get DRI to license the exact Mac interface. Then in six months, with a significant number of PCs running GEM, the Apple marketing people could have come to corporate accounts saying "Look, your people already know how to use our interface. Why not slip our 68000 behind it -- smaller footprint, higher resolution screen, and a cheap network for department-wide laser sharing."

Yes and yes. There is one programmable timer reserved for applications
programs. There is a BIOS routine that allows you to redefine vectors.

My point was not that we should stop talking about the ST on net.micro.atari,
but that one particular discussion (a very partisan comparison of the ST vs.
Amiga) was becoming tiresome. That discussion seems to died down about now,
and I'm looking forward to seeing some more interesting technical discussions
of the ST.

Summary: Replacing the A400 instead of upgrading

Stores around here (Silicon Valley) are closing out Atari 800XLs at
$69.95, and some ads in Antic have Atari 1200XLs at the same price.
At these prices, it would probably be better to get a new Atari (with
more RAM and a better keyboard) than upgrade the 400.

One company is giving a free atari 1200 with every purchase of an
inexpensive dot-matrix printer!

There are several sets of documentation in the package, two of which document
CPM-68K and GEMDOS. MS-DOS is never mentioned, but the GEMDOS system calls

are almost identical to the corresponding MS-DOS calls. The CPM-68K system calls are indeed present, and the development software present came from CPM-68K; however, you are free to use the more powerful GEMDOS calls.
[NOTE: MS-DOS also includes CPM/86 entry points as a subset]

> HOW DO YOU INVOKE THE LINKER ON A FILE "hello.o" which uses the
> documented library function "printf()" and nothing else?

It sounds like your development kit doesn't contain the same files my does. I have batch files to do most of the linking, but not with the titles you mentioned in your note. [I omitted most of your question above because it is so long] Anyway, the answer is:

    To link a TOS application, the basic command is:

    link68 [u] file.68k=gemstart,file.o,gemlib,osbind
    relmod file

Note that all files should be prefixed with whatever drive they are on unless all the files are on the currently selected drive. You can also substitute gems for gemstart, I think some developer's packages have that name. I don't know for sure if osbind is required. You have to add "libf" to the line if you use floating point. [All this was adequately documented in my package, but you didn't seem to get everything from what you said]. Some of the docs were online (like MicroEmacs and the README file). The latter had the linking docs.

The 68K file is the output of the linker, not it's input. The "_printf" symbol, which you couldn't find, is in gemlib. The relmod program takes the CPM 68K output file converts it into a file TOS can load.

**** Additional Note ****

The big "gotcha" in the developer's kit is the fact that the gemstart module only allocates a total of 1K of stack+heap space. You have to edit and reassemble the source to get any more! If you're like me, and try to keep most of your data on the stack (within procedures), that's just not enough. If you run out, you don't get an error message, you just clobber yourself, so I'd suggest you edit the file to give yourself a more liberal workspace before you start on anything fancier than "hello world".

I don't have the technical information to answer the question of interrupt vectors with specifics. But, I do know that the ST can change the color registers scan line by scan line just as the Amiga and old Atari 800 could. This is usually done with "periodic interrupts".

I am trying to program the ST in Hippo C with grossly inadequate documentation about the machine. Can anyone tell me how to read the joystick ports. Also, if any one knows, how do you use the BitBlt capabilities.

John

I work for the company that bought the AMY chip and sound lab from Atari - Sight & Sound Music Software, Inc.

We bought the chip from Atari this summer. Slightly contrary to what John Dvorak and that editor of Atari Explorer says, S & S owns the chip, but Atari reserved the right to buy them from us at foundry prices.

However, that means they can buy the chip at cost, but the deal says
nothing about software drivers and support, so Atari will have to do
this themselves, or contract someone to do it, if they want to put
it in future computers.

We have an XEM prototype board sitting in a box, gathering dust, up
at the office.

Rick

<Bug-eater line>

Having come across a short program which creates music using fractals, and motivated by a program a friend found for generating speech-like sounds on an IBM PC (and having heard an Apple II speak in the distant past), I'm currently beginning to attempt to seek out the outer limits of sound capability of the 8-bit Atari's. I'd like to know of any interesting things you may have done, or may have considered doing but never quite got around to, as a starting point for my investigations. Any programs, algorithms, ideas, or whatnot that you may have lying around would be much appreciated. Please respond by e-mail. I'll post a summary if anyone is interested (and if anybody responds).

I have a certain amount of experience in hooking up extra drives to the Percom...last year I got one of those surplus RX180AB's, and interfaced it without much problem. The same drive was also purchased by friends of mine to hook onto Radio Shack color computers and others. Apple uses a strange disk format/data encoding scheme, but that's all in the controller board and I think the drives are standard.

If you can find a Percom, by the way, BNF Electronics is still selling the RX180's (still in their DEC boxes) .... 2 double density

single sided drives in a very nice cabinet with power supply for
$200 according to the last catalog I have. They're surplus but
brand new. Apparently DEC dumped them when the "stick a micro in
your VT100" campaign flopped.

Drop a line if I can help with more information.

The Atari 830 modem is just a standard Novation CAT 300-baud acoustic modem
with Atari's name on it. The modem has a DB-25 connector and it comes with
a DB-25 to DB-9 cable which is meant for connecting it to an Atari 850 (the
850's serial ports don't use normal-size connectors).

Keywords: Sounds, Music, MIDI

And now for something completely different...

I am very interested in the sound and MIDI-features of the
ST, but I have some questions:

- What are the possibilities of the built in music chip and
  what are the builtin GEMDOS system calls to use them?
  I already recovered the sound(x,vol,pitch,oct) and wave()
  calls, but I don't know yet how to use different voices etc.

- Is this chip really as bad as some people suggest? Then I
  would rather use the MIDI-connections, since I have in mind
  to buy a MIDI-synthesizer soon. Anybody knows of some
  (coming) software for MIDI-applications?

I'd appreciate the experiences and opinions of some other (music)-
interested ST-owners. Thanx,

Raoul.

Patents can only be granted for an invention which is clearly "new" and
"not readily obvious to one familiar with the art" based on previous
inventions in the field.

What areas are covered in the Apple patent on the Mac style screen?
Much of what appears has been in use by Xerox, for one, for some time
either on the Alto, where the screen layout for Draw appears to be very
close to that for Mac's graphics, and on the 8010.

YES!!! IT IS TRUE!!!

In reality the Atari 830 modem is nothing more than a NovaCat 300 baud
modem. It requires the Atari 850 Interface (or other identical device)
to make it work. As for availability, Who Knows? With the exception
of the new Atari ST and XE computers everything else is on a first come
first served basis, since nothing else is being made by Atari, Corp.

<<<<<<<%%%%%%%#######|||||$$$$!!!&&(line^eater)&&!!!$$$$|||||#######%%%%%%%>>>>>>>

The visionary light has gone out of Apple. The company has become yet another short-sighted next-quarter-oriented concern. Does Apple really believe that by forcing DRI to cripple GEMDRAW they are going to sell more MACS? People who buy IBM PCs or compatibles will continue to do so for whatever reasons they buy them today - they are not going to rush out and buy MACS because DRI crippled GEM.

A more visionary Apple might have forseen that GEM, by introducing IBM PC and compatible users to a MAC-like interface, was helping to propagate a standard user interface in the PC industry; in an industry full of incompatibilities, standards are sorely needed, and GEM is/was helping to bring together the MAC world and the IBM compatible world, at least at the user interface level. If only all drawing, painting and desktop programs would confirm to a standard screen display (scroll bars, close boxes, windows of variable size, multiple overlaid windows, etc.) the personal computer industry as a whole would benefit: when users are confronted by a bewildering array of choices, they are turned off and tend to postpone purchase; when faced with an industry standard, they feel more comfortable in going ahead and taking the plunge. This would, in the long run, benefit Apple itself!

Instead, Apple has earned the resentment of personal computer users by its heavy-handed actions. Its efforts at denying user-friendly interfaces for the masses will backfire: Whereas the "MAC-like User Interface" may have soon become the industry standard, displacing anything put out by IBM or Microsoft, Apple has now forfeited that position.

Maybe its not too late. Apple, could you please offer to license your user-interface to all-comers for a nominal sum? You will benefit in the

long run.

They would be able, but unlikely unless you were selling it, or distribution
of your version could be proved to be cutting in on their profits.

> on porting os9 or some unixlike environment to the ST?

I know for a fact that Atari has a project to port Unix to the ST.
It's not very far along yet but it is real Unix. Jack Tramiel is
negotiating with AT&T to hack back the arcane licensing requirements
so he can afford to sell it cheap and still make a profit.

> There has been a *rumor* drifting about (especially among sales people)

> know if this is 1)possible and 2)if anything remotely close to this is
> being worked on?

This is definitely possible but it would be stupid, I think. If
they're going to a 32-bit CPU they should go 68020 since it would be
software compatible. Also if they go to a 32-bit version, they should
let it handle the user interface because (if it's a 68020) it's 2-3
times as fast as the 68000. (Today's buggy National chips are roughly
68000 speed +/- 30%, and their future ones don't touch the 68020.) If
you let the big chip numbercrunch and leave the 68000 moving bits on
the screen, the user interface runs at the same old speed, and face it
guys, what percentage of the time do you crunch numbers versus moving
screen bits anyway? If the 32-bit CPU did both, then both would run
quickly...

  According to the information I got from an ATARI users group meeting earlier this week, ATARI has indeed brought the rights to the UNIX system-V. Nothing is really known, for sure anyway, about AT&T becoming an OEM for the 520ST, but the possibility exists.
  As an aside, the 520TT (32-bit/32-bit) is in the works!!

>Various complaints about arpanet messages sent to usenet people because
>some arpanet machine couldn't contact another to forward a mailing list.

(Put on your asbestos suit. Here it comes.)

This is happening to me too. I once had this happen on net.micro.amiga to

the point where I was getting 8 junk mail messages a day. This happened for two weeks (until the involved computers decided to give up). Frankly, this pisses me off. This is not the way the software should behave. I would think that arpa sites would be more responsible than that. This is not something that needs to be handled on an individual basis. The software needs to be changed to do more intelligent things when a mailing list can't go to a particular machine. The obviously correct thing to do would be to mail notices to the person responsible for the forwarding instead of sending personal mail to the poster of the message. Gatewaying articles into arpanet is a Nice Thing, but this brain-damaged behavior is costing Usenet people a lot of money. They have to pay real phone bills!

I am quite seriously thinking of writing a program to pull such messages out of my mailbox and mail them back to the offending machine. I think maybe if something like that got posted and people started using it then the people responsible would take action to correct it. I wonder how much money has been wasted because of these messages? Think about my case. Eight messages a day containing the entire source of my postings repeated for two weeks. That's 112 junk mails. You want to pay for it? I don't.

(You can remove the asbestos suit now.)

Sean

Many of the folks who are criticizing Apple for givin DRI trouble may
not be aware of what some Apple employees have told me is one reason for
this action. GEM just isn't a good system. The fact that it resembles
the Macintosh/Lisa cosmetically could easily turn a lot of people off
to that whole style of working just because of the inadequacy of
the DRI design/implementation. I don't think that this has any
bearing on the legal issues, but from the standpoint of Apple's
motivation, I find it easy to believe that they would not want what I
(and apparently, they) consider a second-rate "desktop-style" system
to be the standard on many machines. No one is going to switch to a
Macintosh if they are led to believe that GEM is typical of a state of
the art desktop system.

Yes. All of them. As well as ATARI and APPLE. I just haven't thought of any
good slanderous names for theit operating systems yet.

> I don't like Commodore's DOS (I assume
> that's the first one you meant), but the Shack's DOS is quite good. In
> fact, probably better than the Amiga DOS from what I've heard so far.

Not if it doesn't multitask it isn't. If it doesn't multitask it doesn't
qualify for the name "operating system". An operating system should have
a memory manager and a scheduler as well as a file server and device drivers.

> I'll reserve judgement. MS-DOS isn't that bad either. It could have
> been better, but it's development was originally an outgrowth of CP/M.

I rest my case (good thing, too. It was getting pretty heavy).

>   As for other 'little computer "operating systems"', ahem, like
> Unix maybe? Or OS-9? I have heard *nothing* which indicates *any*
> superiority of AMIGAdos as such over OS-9 in *any* way. But, mainly

Both of them are real operating systems, instead of "DOS"es. And neither of
them are widely available on a home computer. I know you can get OS/9 on a
CoCo, but I still have yet to see one in action... and it's severely limited
on that little machine. I'd much prefer a 68000 with OS/9 or UNIX, but I'm
not likely to afford one on my budget.

Atari Corp. has purchased the licence for unix system V, but I don't
really know what they intend to do with it. They may try to host a
derivative on the 520ST or they may target it for the 520TT (32/32bit).
Time will tell...

If you copied pac man and gave it away, they can still sue you and sometimes
they do. There are various precedents in the copyright laws where people
were fined substantial (c 10,000 dollar) amounts for photocopying literary
works and posting the copies on bulletin boards. (Watch out Dave Berry
posters...) I am not sure just what has happened in the software world yet.

According to Computer Systems News, 10/21/85, page 8 Atari has signed
a Unix System V source license. The article states that Unix will
be on the 1040ST (1040??) which "is slated to be unveiled during the
first quarter of 1986" and "on the company's long-promised 32 bit line."
It will not be on the 520ST (unless a third party does it).

Sears is selling Ataris real cheap - 600XL for $34.99, and 800XL
for $49.99. Oddly, the prices on the display models had not been
changed for months. One sign for the 800XL read $179.99 and
another $69.99. Is this a sophisticated marketing technique?

Since the 600XL ($35) and 1200XL (free) are so cheap they are
great candidates for modification/augmentation. For about $5
one should be able to bring the 600XL up to 64K giving it 800XL
capability (but no monitor output) in a smaller package. Another
idea is to "compatibalize" the 1200XL by replacing the OS ROM
with 400/800 ROMS (widely and cheaply available).

Has anyone undertaken either of these projects?

Jim

At an users group meeting in Seattle last Monday attended by some
Atari brass (including Leonard Tramiel) they said that Unix will
be coming in 5-6 months. From my understanding of their answers
to several questions the Unix system will be primarily directed
towards the next ST (the 1040???) but it will run on the 520 if
you have expanded its memory.

There is a company in Connecticut (CT. Microsystems?) that is seriously
considering porting OS9/68K to the ST. I have not heard whether or not
a final decision has been made yet.

Atari has announced (at least informally; it was at an users group meeting
attended by some of their top executives) that they will be supporting
Unix in 5-6 months.

The 32-bit add on to the ST will attach to the 10 Megabit DMA channel
on the back of the ST. The 68020 is under consideration for the system;
its main drawbacks are compatibility problems for system mode software
(and presumably price).

The "50,000 sales" number is supposedly the rough sales figure for ST's worldwide as of 1-2 months ago.

****

I have read zillions of messages concerning the audio chips of the Amiga,
but nothing about the ST. The ST's I've played with have been absolutely
silent. Is there any sound capability at all? If so, is there an internal
speaker, or must (can) the sounds be played through a stereo or amplifier?
(Does the RGB monitor have a built in speaker?)

...I'll summarize mail responses to the net.

I believe it is a 1200XL keyboard. It is not compatible as-is with your
400. Probably you could strip off the components and wire your own
matrix. I didn't find that to be too difficult, but I started with a
clean keyboard.

   The local Atari user's group Hardware SIG has two working 256K 800XLs.
I saw them demo'd at both the SIG and general meetings. They work;
however, I think they found that the Byte article wasn't 100% accurate,
but since they have the hardware knowledge, have done there own modifications,
and also have modified DOS 2.5 to work properly. The good news is that
we (the User's Group) have made both the circuit diagrams and the DOS
patches Public Domain. I'm not sure how you, as a member of the public,
would go about getting this information, but since I'm here on the net
and a member of the AUG, I'll take names of interested people and see what
I can do. (If you ARE a member of some Atari user's group, it might be easier
to ask your chairman or secretary or whatever to get ahold of my chairman or
secretary or whatever, and request the info. Here's the address:

          Madison Area Atari Users Group (MAAUG)
          Post Office Box 56191
          Madison, WI 53705

Further news: they haven't yet made a 256K 1200XL, but they've opened one
up and said it can be done, but you also have to buy, um, it was either an
Antic or GTIA chip (I forgot which one; probably the former). Also, they
believe it's possible to cram an *extra* 256K into these machines. Yup!
That's 512K! And as the icing on the cake, our chairman, when last seen,
was mumbling something about "Directly accessing memory... forget about
ramdisks... piece o' cake..."

Try this:

     link68 [s,u] gemstart,PROG,gemlib,libf

I think that's all of them. I've managed to get a simple program that reads the MIDI port and prints the hex byte to the screen working. The libf library resolves the atof() and etoa() undefined errors.

You also have to be careful when passing arguments because the C compiler does not automatically convert everything to long words when passing arguments on the stack. chars and ints use MOV.W data,(SP)- and pointers and longs use MOV.L data,(SP)-. This can can a crash due to bus errors because if you're not careful you could pick up an invalid pointer.

Don't ask me why they decided to do it this way, probably just to cut down on generated code and improve speed, but it definately will cause problems with LOTS of software that assumes that arguments passed to function are the same size and resized to the proper size by the called function.

I was just over at the Atari store looking at the $27 modem, it looks good,
it plugs into the serial loop (back of the disk drive) and comes with window
software on disk which allows you to configure, print screen and xfer files
using xmodem protocal, it also has autodial with the ability to save a
directory of numbers. it also comes with a packet of free time on
compu-serve and dow-jones new retrival service. only one down side, best i
can tell its 300 baud only but for $27 who cares !!!!!--

the ST uses a standard video game type chip from GI (general instruments) i
cant remember the number right now but i have the user manual and will be
glad to send you a copy if you wish. it is a 2 voice chip and can produce
music and decent video game type sounds, but sure aint the Amiga or even the
C64 sound chip.

*** REPLACE THIS LINE WITH YOUR RESULTS ***

Some Facts:

The Amiga reads a 32K file in
     4.39 seconds

The Amiga writes a 32K file in
     6.20 seconds

The Amiga draws
     142,020 pixels/second

A Challenge
     Do the following tests on your favorite computer, and POST the results.
     May the best computer win!!!

The Algorithms:

The following algorithm was done on the Amiga with the native Lattice C
Compiler. It writes 64 512 byte buffers, then reads 64 512 byte buffers.

```
for (i = 0; i < 512; i++) p[i] = 'a';
fp = fopen("df0:data", "w");
CurrentTime(&Seconds, &Micros);
for (i = 0; i < 64; i++)
  nact = fwrite(p, 512, 1, fp);
ret = fclose(fp);
CurrentTime(&Seconds2, &Micros2);
printf("%d %d %d %d", Seconds, Seconds2, Micros, Micros2);

fp = fopen("df0:data", "r");
CurrentTime(&Seconds, &Micros);
for (i = 0; i < 64; i++)
  nact = fread(p, 512, 1, fp);
```

```
ret = fclose(fp);
CurrentTime(&Seconds2, &Micros2);
printf("%d %d %d %d", Seconds, Seconds2, Micros, Micros2);
```

A while back the following message was posted to net.micro.mac:

```
>From: saldana@cernvax.UUCP (saldana)
Newsgroups: net.micro.mac
Subject: Mac line drawspeed
Message-ID: <198@cernvax.UUCP>
Date: 9 Aug 85 00:56:15 GMT

I made a benchmark to find out how many pixel/sec a Mac
could draw. I also ran the same benchmark on the Apollo
workstations we have.

Algorithm:
/* draw 8000 vectors of 200 pixels long with a skew. set by offset */

x1 = 100 - offset;
y1 = 100
x2 = 100 + offset
y2 = 300

for (i = 0; i < 20; i++) {
        PenPat(black);
        for (j = 0; j < 200; j++) {
                MoveTo(x1, y1);
                LineTo(x2, y2);
                x1++;
                x2++;
        }
        PenPat(white);
        for (j = 0; j < 200; j++) {
                MoveTo(x1, y1);
                LineTo(x2, y2);
                x1--;
                x2--;
        }
}

results:

****************** Rich Rodgers Amiga results ******************************

Amiga (68000, Lattice C)
                   offset = 0    139,542 pix/sec
                          = 1    142,020 pix/sec
                          = 20   142,020 pix/sec
                          = 100  142,020 pix/sec
```

****************** Rich Rodgers Amiga results ******************************

[sacrifice to line eater bug -- patent pending]

Yesterday I got a first hand example of why Apple is upset about
GEM. I was out at one of the national computer chain's store
here in town, and found all the Macintosh software shoved in
with the IBM versions of GEM software.

I went to 3 other stores, where they barely seemed to have heard
of the Macintosh (but were happy to sell me all the copies of
1-2-3 I could handle).

While they may not be justified in claiming the "look" as a
thing which can be owned (tho there *is* some legal precedent for
such claims), they are certainly justified in
worrying about people thinking it runs on a Macintosh.
Every week I talk to people who want to know if you can put
a Macintosh disk into an Apple II, or if their old Commodore
software can work on an IBM PC.

In response to the flame to John Demar's comments,

John Demar (JD):
     The ST brings in a 32K file
     in less than 4 seconds, including drive start up,
     directory search, etc. The Amiga takes almost 20 seconds!!

Gary Girzon (GG):
     That is just not true! The BYTE Basic benchmark for reading and
     writting a 64k file takes 25 seconds. And this is in basic!
     Please check or tell us how you arrived at these figures.

JD: I'm a software/hardware developer and an electronics engineer.
     I've seen and used computers from $50 to $5Million and have designed
     VLSI chips for 6 years at GE until starting my business last year.
     So, the following is said from technical expertise and not
     first-impression judgments from marketing "fluff"...
     I own (or have owned) both the Atari 520ST and Amiga PC. I've given
     them both a good bit of work and inspection, including o/s design and
     hardware architecture. Here are some facts and my conclusion:...

I: Under these circumstances I tend to believe Demar more so than BYTE.
    Without citing, I have read some of Byte's previous benchmarks, that
    were misleading, but this is really irrelevant.
    By the way, Is this J. Demar the same J. Demar who wrote some of those
    Blackburg series books?

JD(cont):...the amiga has a non-standard disk configuration and does
    much of the disk support in software (ie. slow). The drives have
    slightly more capacity than the the ST's DS drives (880K to 720K) but
    this is at the expense of speed. The Amiga directory format (or
    lack of) is done much like a commodore-64. In fact, to get a
    directory, the Amiga goes out and finds a program called DIR,
    loads it and goes back searching!

I: If that is true, I have lost all respect for AmigaDOS.

GG: ...Unless the ST has some sort of dual-ported RAM, the screen data
    must come from the same data bus in the ST as well.

JD: ..First, there are a pair of chips working together to optimize
    data bus and screen data access. The memory controller
    prefetches 16-bit data directly for the 68000 and also places
    screen data onto a separate bus for the screen refresh chip. This
    operation only steals 8-18% of the available true CPU time.

GG: If you measure a computer's worth by the number of chips,
    you might as well pick an IBM over a Mac. Perhaps the custom chips
    in the AMIGA are better integrated to perform several functions in one
    chip. Thus you do not need MORE chips if three can do the job.

I: non sequatur (sp?)

JD: In the low res mode, those fantastic graphics chips
    steal almost 70% (yes!) of the possible CPU time that the 68000
    could be using to do real computer things like calculate,
    move/sort data...

GG: How does one arrive at the magic 70% time figure? Also, the 68000
    in the Amiga does not draw lines, polygons or fill areas.
    It is done by one of the coprocessors. SO the 6800 (???) can
    do "real" computer things.

I: I would also like to know how Demar got the 70% figure.

JD: The windows are poorly configured and move with flicker.

GG: They do? Not in my AMIGA.

I: Maybe they do in his AMIGA.

Sorry for the redundancy in the quotes.

The ST would make a nice sampler if it had enough resolution. The
Emu-lator for instance has 12 bit resolution, the ST only 8 (but, was it
the old Atari machines that had a 16 bit playback mode?). Of course the
68000 at 8MHz is pretty powerful; one could imagine a trivial board that
would do adequate conversion.

Bear in mind that the ST gives you the inexpensive part of a
synthesizer, the board with the chips on it. A keyboard instrument
usually also has a keyboard. Good ones are expensive. Unless you'd
like to play your next piece on a QWERTY?

Could you please post more information about your RAM disk?
In particular I would like to know what you did for a memory upgrade -
did you buy a kit or was it a homebrew project?
Also, where did you get the software for the RAM disk? Is someone selling
it, or did you write it yourself?

Sorry for all of the questions, but I am getting my developers kit next week
and I need all the information that I can get. Any pointers would be
appreciated.

Thanks in advance,

A couple of weeks ago a news article appeared in this newsgroup concerning
a 1MB memory upgrade board that someone was going to build and sell.
This board would be upgradeable to a 4MB expansion when 1Mbit chips
become readily available. The artice consisted of some correspondence
that had taken place on Compuserve. This product was to have been
available sometime in October.

Does anyone have any more news of this development? I, for one,
would be very interested in such a product.

(To add more fuel to the Amiga vs. Atari 520ST debate.)

Excerpted from the November _Creative Computing_, in
"Outpost: Atari" - of all places:

   "After months of waiting for my new Atari 520ST system, it arrival was
almost anticlimactic.... As with any new computer product, the first units
would have more problems and less software than more established machines.
The price would no doubt be higher at first...."

   "...As I hooked up the system and turned it on, my disinterested facade
began to crumble. Since the operating system is not yet available in ROM,
I had ample opportunity to check the transfer speed of the disk drive as it

loaded TOS from disk. The ST loaded the entire 200K+ file in about 25 seconds...."

"[Author states the monochrome screen is very nice...]"

"Unfortunately, the feeling of euphoria did not last long, as I realized I had no way toput the ST through its paces. The only software I had was Logo- a version so slow that I wondered if the interpreter was written in Logo. The fact that I had sprung $1700 to buy the developer's package hardly made me better off than the average buyer. Although the package came with development software like a C compiler and assembler, it was essentially useless out of the box, because the text editor needed for writing programs was to be sent out later by the manufacturer (apparently much later, since six weeks after getting the machine, I'm still waiting.)

"Moreover, the celebrated 6" stack of documentation that comes with the development package turned out to contain more hints than answers. The bulk of the material consisted mainly of photocopies of Digital Research document-ation, that, though somewhat related to the machine, was by no means ST specific

These included a CP/M 68K manual and the full manual for development of GEM on the IBM PC. Only a few pages of the documentation came from Atari, including some sketchy material on the BIOS routines, the keyboard, printer codes, and source code listing for the boot ROMS. Of the 1500 or so pages included, more material was devoted to the Kermit protocol file transfer program than to the ST."

What I mean to say by all this is... a $1700 ST development system like that presented above is by *no means* superior to a comparable $1700 Amiga Developer's system. A lot of 'Atarians' though have spat hellfire, though, trying to substantiate that claim.

The ST appears to be a nice, homey monochrome, and some-color graphics machine, when compared to the more expensive, but certainly more powerful Amiga. ST drives really are slower, and hold less- than the Amiga's- no matter what some 'special' people say.

Both of the speed problems, as an example, will probably be fixed once the software of both machines can get a decent looking over by technicians who were rushing the machines to the marketplace.

D. Rosenberg @ ATT/BTL Murray Hill "These Are... My Opinions."

The October 7 issue of Infoworld carries an article on the Apple-DRI affair which notes that:

> "DRI has agreed to pay an undisclosed monetary settlement to Apple as well as provide programming services for Apple at a reduced rate."

The article also notes the observation of Batteries Included's Michael Reichmann that:

> "Apple is going after everybody. Commodore and Amiga, Microsoft for Windows - even Mouse Systems for PC Paint, because it looks like MacPaint."

Unless I am missing something, it appears to me that Apple is giving up on attempting to compete in the American small computer market, for which it very obviously lacks the brains and talent, and simply intends to survive by preying upon and extorting money from companies such as Atari and Commodore which have no such lack.

THE 64,000 DOLLAR QUESTION: Is anybody from Xerox reading this? I would, upon recieving a request from an official representative of Xerox, gladly donate $25 to a fund to be used for the purpose of suing Apple for their flagrant copying of the "look and feel" of the 8010 Star. I could very easily justify such a donation as an investment in the American free-enterprise system.

A week or two ago, someone posted an article describing errors during
start-up of the ST. I had the same problems when I first got my ST; a
row of little bugs would appear across the middle of the screen and
everything stopped. One POSSIBLE explanation for this is that the disk
is too close to the video monitor.

In an article re-posted to the net concerning the use of 5.25" floppies on
the ST, the author mentioned that the ST video monitor puts out unusally
high magnetic fields. This might affect the read/write heads on the drive.

I had my floppy drive right next to the monitor when I got these errors
and after I moved the drive a foot or so away from the monitor I have
not had any more problems.

Funny, you complain 'that if one is to compare the AMIGA and the ST, at
least one should have used both', but you say you don't have an ST, so how
can you compare the two. I talked to John about this (before I saw this
message) and I can tell you that he had both machines and did side by side
comparisons. AMIGA user's might not like to hear it, but the ST is faster
(at least in raw computing power, it remain to be seen how graphic programs
would compare, but I would put my money on the ST for most aplications due
to the AMIGA losing so many cycles for commands to the graphics chips). I
don't have any direct experience with the AMIGA, so I can't make any direct
claims. I think there is a place for both machines, but I'm putting my money
on (an into) the ST.

       - Clint

These are my own opinions and those of my employer :-)

Could you clarify this point? I was under the impression that the Mac operating system was simply a standard CP/M like system with a BIOS/BDOS (whatever they call the DOS), a CCP (the finder), and a TPA. The way Switcher works (almost exactly like DoubleDos on the IBM) makes this painfully obvious. I was also under the impression that an Object Oriented system would be capable of many things the Mac isn't able to do, such as allowing an arbitrary number of co-resident programs ala SmallTalk, which would of course make Switcher rather redundant. Are you implying that the Mac is an Object Oriented system of the SmallTalk genre, as well as having a SmallTalk-like user interface?

Also, what is an "Action Oriented" system in this context?

Because it is a VT100 emulator, mostly. It has ASCII upload and
download capabilities, with delays, echo prompts, etc. Also Modem7, and
as you mention, Kermit. Auto-dial strings programmable, function keys
can send pre-defined key sequences, "history" mode where you can scroll
back through the stuff you've been sent, printer controller mode, and
some other less important stuff. But mostly because it is a VT100
emulator.

I work for Mark of the Unicorn, so the things I say might be biased.
But I'm only allowed to answer technical questions, so there's little
enough room for bias.

              November, 1985 ANTIC TOC
              Theme: New Communications

Page Article

10 ANTIC ONLINE
Regular monthly feature on BBS's including PALTO's new toll free number (800-328-7104) and rates ($7.75 per hour for either 300 or 1200 baud). Does anyone know whatever happened to the Learning Cartridge?
12 ST USES IBM DISK FILES
A description of how to hook a generic 5.25 inch disk drive up to your ST and how to transfer IBM PC text and binary files into the ST.
16 ST SOUND
A discussion of the AY-3-8910 sound chip used in the ST and a type-in demo written in C.
20 C.O.L.R. OBJECT EDITOR
A discussion of the object editor developed by the Rugby Circle company. They are converting some software for the ST (including JOUST) and developed this editor for their own use but it is now available through ANTIC as a program in their catalog.
22 READER'S FIRST ST PROGRAMS
Two very short demos written by Fred Hatfield.
26 TYPO II DOUBLE FEATURE
Two updated enhanced versions of the error checker that ANTIC readers use to check the programs they type in from ANTIC magazine.
28 130XE MEMORY MANAGEMENT
A complete explanation of the extended 64K RAM in the ATARI 130XE, by Ian Chadwick, author of 'Mapping The Atari'. Includes a tutorial program showing how to access the extra memory from BASIC.
33 RAPID GRAPHICS CONVERTER
Convert your picture files between any commercial ATARI graphics formats--in less than 60 seconds. Supports Micro Illustrator, Micropainter, Fun With Art, Paint, Visualizer, Moviemaker, Graphics Master, Atarigraphics and Graphics Machine.
36 RADIO ATARI CALLING
A discussion of how HAMS are using computers to control and use satellites, slow scan video, repeater stations and more.
38 RADIO MODEMS AND SOFTWARE
A discussion of the hardware and software available to allow you to receive RTTY using your ATARI.
41 MORSE CODE RECEIVER
Software that translates Morse Code into ASCII values which your ATARI displays as characters or numbers. BASIC. Need to build hardware interface.
44 KYAN PASCAL
A review of this software by Kyan Software. ANTIC calls it "true PASCAL for ATARI, at last".
49 GAME OF THE MONTH: VAMPIRE RATS
In honor of Halloween, one of the strangest arcade games ANTIC has ever published. BASIC.
51 SOFTWARE LIBRARY

All the listings for the programs in this Issue are located together for easy finding.

70 ASSEMBLY LANGUAGE: FAST MOVES
Learn how to change the keyboard repeat rate on your XL or XE and speed up the cursor on any 8-bit ATARI. BASIC makes autorun.sys file when run.

74 PRODUCT REVIEWS
Software:
- Great Cross-Country Road Race (Activision,Inc)
- ANKH (Datamost)
- Simax Video Signmaker (Jack Bellis)
- Mindwheel (Synapse Software division of Broderbund)
- Final Legacy (Atari Corp)
- Chopper Hunt (Imagic)

81 NEW PRODUCTS
Announcements of some of the latest available software and hardware for ATARI.

Comments: ANTIC states that Microbits Peripheral Products (MMP) legally went out of business but were bought by SUPRA CORP which is run by the same two guys that started MMP (confused?). They still carry the same products and still plan to release the 1200 bps modem, MicroNet and the $800 10MEG hard disk. The use of the 5.25 disk drive mentioned in the article on page 12 requires the modifying of the 3.25 disk drive that will void the warranty. There are other ways to do this as mentioned on the net. This issue is a must for HAM radio operators. There are several additions to the ANTIC software catalog including C.O.L.R. and two public domain disks for the ST. I will be updating my listing for their catalog soon (promise). Happy reading. See you next month.

In article <299@ccivax.UUCP> rb@ccivax.UUCP (rex ballard) writes:
>I find it rather hard to believe that Apple would really have a case against
>DRI.

>True, in terms of it's external appearance, the GEM interface looks very
>much like the Mac interface.

These comments are mutually exclusive.... The case was specifically for the visual copyright, so looking too much like the Mac was exactly what Apple was (deservedly) upset about. If you spend 25 man years making someone, and someone else borrows your design, does it in 5 many years, charges less, and puts you out of business, wouldn't you be upset? Business needs to be able to protect its R&D or R&D simply won't get done.

>But things like binding (install application)
>are much different.

This also has nothing to do with the visual copyright....

> I see Apple's possiveness of "Pull Down Menus" and
>such as a little like trying to Trademark each letter of the alphabet
>and expecting to collect royalties.

Why? If I was the first to design an algorithm and got protection for it, I'd expect to be able to protect it.... If I invented an alphabet, I'd sure want royalties for it... That is an easy statement to make, I'd love to see you back it up with a good reason.

>Patent, Trademark, and Copywright laws were designed to promote creativity.
>In fact, the current laws, as used and interpreted by the computer industry
>are being used to stifle creativity.

Can you prove that? Again, if I spend my R&D budget designing a new nifty, and someone else takes a copy of my nifty, redesigns it, and puts me out of business, how in the hell was that creative? That is what apple is trying to prevent -- if they wrote GEM to be better than Mac, fine -- but if all they did was take what Mac developed and carry it across, that is frankly illegal.

>If a playwright wants to create a script from a novelist, he gets a "royalty

>agreement" from the novelist. Often, patent rights are "traded" between
>competing companies.

If GEM had set up an agreement with Apple, they wouldn't be IN this
position. They just took.

>Apple (Jobs) wanted to dictate the industry standards for this
>(Icons & windows) generation of computers. They succeded to a point,
>now they want to collect. It's a little like putting Kermit or FIDO
>in public domain for a few years, then expecting to collect royalties
>for those copies distributed as public domain.

Huh? Apple never put ANY of that stuff in the public domain, and never
pretended to. Also, there happens to be a good precedent for public domain
stuff -- Emacs. You can still get an old, crufty version of PD emacs if you
want it, or you can buy a significantly improved version from CCA or
Unipress (or you can hack on GNU, just to be complete). But that has
NOTHING to do with what apple is doing... I wish we could keep our facts
straight, folks, instead of these purely emotional rantings...

>>
>from what i hear (from inside a certain company involved in this) DRI is
>just plain chicken and doesnt want to risk a lawsuit

When I was out at Apple last fall, they told me they had a patent on
that type of interface. I'm not sure that this is correct, but that's
what they said. If it is the case, they could certainly claim that
DRI was copying the "look and feel" of the Mac interface.

Well, there was an Amiga at our (somewhat sucessful) computerfest today, sponsored by the University Personal Computing Assoc. (of which I am an officer) as well as 5 or 6 ST's and a lot of demos, so I'd like to expand on some of this discussion.

GG: ...Unless the ST has some sort of dual-ported RAM, the screen data must come from the same data bus in the ST as well.

JD: ..First, there are a pair of chips working together to optimize data bus and screen data access. The memory controller prefetches 16-bit data directly for the 68000 and also places screen data onto a separate bus for the screen refresh chip. This operation only steals 8-18% of the available true CPU time.

GG: If you measure a computer's worth by the number of chips, you might as well pick an IBM over a Mac. Perhaps the custom chips in the AMIGA are better integrated to perform several functions in one chip. Thus you do not need MORE chips if three can do the job.

GF: non sequatur (sp?)

myself: Regardless of the memory arrangement, I found the ST's graphics to appear intrinsically clearer. Perhaps Atari uses a better monitor, or maybe they tighten up the dot edges, but the amiga's graphics had a fuzzier, blurrier, yet warmer appearance. For data, I would have gone with the Atari's no-nonsense display, but the Amiga DOES do an impressive job on pre-drawn graphics, and the color text display is less objectionable than Atari's. As for the chips, well, maybe the IBM DOES have more chips than a Mac, or than the //e, but remember...all those PALs and semicustom gate arrays DO replace lots of so-called-glue. Remember how Apple's MMU and IOU replace some 140-odd chips? And since when did manufacturers stop bragging about how many gates and transistors they've packed into the latest design?

JD: The windows are poorly configured and move with flicker.

GG: They do? Not in my AMIGA.

GF: Maybe they do in his AMIGA.

myself: They sure didn't in the Amiga at the 'fest. In fact, I was very impressed (in terms of graphics power) when, while running the 'robo-city' demo (two characters and a dog walk across the screen behind an animated hydrant) the person at the Amiga 'grabbed' the entire page and slid it off the bottom of the screen while the demo was running. No flicker. No redrawing. In fact, the demo kept running at the same pace while we ran its window all over the place. Very nice, but there was severe flicker on horizontal white lines in 640x400 mode, and while not apparent in solid areas, a violent flicker appeared in heavily colored/dithered spots on some screen captured shots. No, I don't mean slightly grey edges. The dots literally shook.

caveats...the salesman tried to explain that the system unit had 512k in it,
     but he included the ram in the kickstart. Unlike the Atari, when you
     get your system roms, you'll find yourself back to 256k. Because they
     won't build the extra in after it's served its usefulness. Also, the
     much-ballyhooed bouncing ball demo, although fun to look at, was not
     that impressive. The 'thud' sound probably contributed to 60% of the
     effect, simply because it sounded massive. But the shadow and ball
     both moved on the same path, at fixed velocity, and the only surface
     animation was a set of checkerboard bands rotating constantly on the
     ball. Reminded me of a Mindset without flicker. The Atari booth,
     on the other hand, showed some simpler, safer graphics, but then
     again, what do you use real-time graphics for? I found the Atari
     to be adequate (and very cheap).

overrunning my expected line-limit,
-dave

>matter what some 'special' people say.

Either this guy did a sloppy review or it is a combination of things
that he has heard from other people as evidenced by the above
contradiction. Yes the ST disks have marginally less capacity 720k(DSDD)
vs 880k(DSDD) but having seen both systems reboot and startup programs
the amiga seems a factor of two slower. Since both computers use
dma for disk access the only explanation for this must lie in the
software or the disk format.

>six weeks after getting the machine, I'm still waiting.)

This seems to be very dated. When I recieved my developers package I
also did not get an editor, but a call to atari solved that problem
as they sent an updated bios guide and a copy of micro emacs. They
were probably in the middle of switching from mince to micro emacs.
In any case this fellow seems more interested in creating gripes than
attempting to resolve his problem through proper channels. A recent
article outlines what is in the developers package and an editor is
certainly listed.

>These included a CP/M 68K manual and the full manual for development of GEM
>on the IBM PC. Only a few pages of the documentation came from Atari,
>including some sketchy material on the BIOS routines, the keyboard, printer
>codes, and source code listing for the boot ROMS. Of the 1500 or so pages
>included, more material was devoted to the Kermit protocol file transfer
>program than to the ST."

My initial reaction to seeing the entire kermit manual was similar. But
again this fellow seems to have never bothered to dig any deeper. Yes,
the GEM examples are for the ibm pc but the description of the bindings
are entirely applicable to the ST. The few routines that are not
available are clearly marked as optional and not necessary to an
implementation of GEM. I have found that most things work as
advertised except for a few compiler bugs that could be worked

around. The bios routines are clearly specified although a few of
the names were modified slightly in the header files. My only
complaint is that compiles take so long on a floppy system. I
have solved that problem however by upgrading to 1meg and doing
everything on the ramdisk.

I have no objection to people posting reviews, but may I suggest
a little quality control. I think misinformation confuses what
should be an open and healthy debate.

>"shell" environment.

The ST *does* have an alternative to GEM in two forms (that i know of):

1) Command.com - which is included with the developer's kit.
2) commercial shells - for example a shell is supplied with Haba C and allows various unix-like commands such as ls,rm,mv,cp,etc...and redirection. It also includes a set of unix-like directories such as usr,bin,lib, etc. You may add commands to your shell by putting the executable to your new commands in bin.

These are the only two shells I am aware of but they do offer an alternative to GEM.

I believe Aztec C offers a very nice unix-like shell for the Mac and will soon offer it for the Amiga (according to the sales rep i talked to they are also planning on Aztec C for the ST).
(by the way i am in NO way affiliated with Aztec...)

By the way I am one of those people that believe both Commodore/Amiga and Atari made a mistake by not putting some form of windowing OS9 into their machines. Hopefully this will come but why didn't they save us all alot of trouble.

Sidelight: in command.com - ls and cat seem to work on my version?? One day i forgot i was no longer on unix typed in ls and it worked! must be some kind of alias.

> I: If that is true, I have lost all respect for AmigaDOS.

I think what he means to say is that "DIR" is an external program, like UNIX' ls, not a built-in like MS-DOS' "dir". To get a directory in CLI it loads a file called ":/c/Dir" and executes it. Since there are disks without CLI *or* dir on them, and they do have directories, it's pretty obvious that they're not hidden inside a program. Especially not one that's itself 2 levels deep in the directory tree. I would like to suggest that Mr. Demar is less than well acquainted with the machine...

And why wasn't net.micro.amiga included in the distribution of this message? Maybe because some people who actually *have* an Amiga and understand it are more likely to respond to it?

Anyway... you can regain your respect for AMIGAdos. It's not UNIX by any means, but it is certainly an improvement over Crummy-Dos, Trash-Dos, Messy-Dos, or any of the other little computer "operating systems".

On the other hand the 520 emulates a vt52 (vt100 is coming)  gratis as part
of the OS, so kermit automatically runs in vt52 emulation mode

If memory serves me right, in the final days of the old Atari, they spent
more time sueing (suing?) companies than anything else. Maybe its a kinda
final gasp....

Keywords: ST, sound, yuck

(Put this in your pipe and smoke it, Line Eater.)

Warning: almost-flame---

I'm sorry my previous message turned out blank. Here it is again:

Thanks to those of you who responded to my query about the ST sound chip!
However, I was dismayed when I learned that it is an AY-3-8910. I have
used this (or similar) chip for several years in peripherals for my Apple.
It is better than what's built in to the Apple, but for Atari it's a step
backwards. The Atari 800 Pokey chip was definitely much better.

Pokey	AY-3-8910
4 voices	3 voices
or 2 voices with 65536 possible frequencies	only 4096 frequencies
programmable waveform (with some difficulty)	icky square waves only

After reading about the Amiga with FM synthesis, and playing with a Mac with
completely programmable waveforms and 4 voices, I was depressed to see that
the ST chip could produce only square waves.

Since it produces only square waves, the 8910 can not make realistic or
pleasant sounds. Since it has only 4096 possible "tone periods", high
pitched notes are inherently out of tune. The white noise generator is
not random enough- you can sometimes hear tones in it. The built-in
envelope generator is handy when you are first learning to use the 8910,
but its envelopes turn out not to be very useful in general- the shapes
are not natural, and they can only be applied to all 3 voices together.
Happily, it is possible to manually produce any envelope by changing the
amplitude parameters "on the fly". With only 16 possible amplitudes,
you can hear the steps in volume as a note decays slowly.

In summary: the 8910 is easy to use but not at all suitable for music or
realistic/natural sounds.

I may have some tutorial articles that I wrote on programming the 8910
on a disk somewhere... I will post or mail them if anyone's interested.
They are intended for the Apple Mockingboard, but the same concepts apply.

I hope that someone comes out with a cheap MIDI device which is to the ST
what the Mockinboard was to the Apple... becoming a defacto standard for
better sound effects so programmers will have something nice to work with.
If it's not cheap enough, nobody will buy it and programmers won't bother.
On the other hand, it must be good enough to be worthwhile (at LEAST

should have programmable waveforms) and good enough that it does not have
any competition- competition would ruin the possibility of a standard for
ST sound appearing quickly.

......Ranjit Bhatnagar   (hoping to buy an ST or Amiga soon!)

Sam,
OMNIVIEW XL is the only 80 column conversion available for your 800XL.
It costs $59.95 and will work with amodem but will require some work.
See my add (CDY Consulting) in the latest Analog.

In fact, the matrix on the 1200XL keyboard is the same as for the 400.
Adapting it for the 400 requires removing the 2 ICs on the board and
soldering jumpers from the (now) empty holes to the keyboard socket
in the 400. One can figure out how to do this by reverse engineering
the membrane keyboard or via the Tech. Ref. Manual.

Sorry if this is a reposting: I haven't been able to keep up with all
the ST mail lately. However,   Robert Ling <rling@uw-june.arpa>
mentioned seeing funnies on the screen upon booting.

According to our local Atari Club (ACORN) newsletter (the "Kernel"),
ST's have been shipped with two-sided sticky tape holding some of the
chips into their sockets. Unfortunately during shipping the tape
expands, forcing these chips OUT of their sockets. The solution is to
open the case (after getting the go-ahead from your warrantor), remove
the chips, peal off the sticky tape, and reseat the chips. Do this for
one chip at a time so you don't swap chips, and be sure to note the
orientation.

Thank you very much.

Incidently, I am currently developing software for the 520ST and will eventually be doing so for the Amiga as well. Does anyone out there agree with me that this whole 520ST v.s. Amiga thing is ridiculous? After all, if you were originally an "Atarian", then perhaps you should realize that the Amiga was designed in part by one of the original designers of the old 400/800 series. And for those of you who consider themselves "Commodorians", remember that Jack Tramiel is now the owner and driving force of Atari.

It does seem a bit silly, does it not?

Remember, ATARI is trying to shed the 'game machine' image. I believe they deliberately avoided the sprites (not needed anyway) and super sound to show they are serious about producing a machine that will be considered for business and other serious applications. I think this will hurt a little bit when they bring out the 260STD because that machine will be bought primarily for people to use at home and they will want to play games and have great sound. Only time will tell.

"Do the following tests on your favorite computer, and POST the results. ... /* draw 8000 vectors of 200 pixels long with a skew. set by offset */"

Well, here are some numbers from my favorite computer, a Xerox 1108 (Dandelion) running Interlisp-D (Intermezzo release) with the following translation of the C code given:

```
(LAMBDA (OFFSET)
     (PROG ((X1 100)
          (Y1 100)
          (X2 100)
          (Y2 300))
          (add X1 (IMINUS OFFSET))
          (add X2 OFFSET)
          (for I to 20
             do (for J to 200 do (DRAWLINE X1 Y1 X2 Y2 1 (QUOTE REPLACE)
TWINDOW)
                  (add X1 1)
                  (add X2 1))
                  (for J to 200 do (DRAWLINE X1 Y1 X2 Y2 1 (QUOTE ERASE)
TWINDOW)
                  (add X1 -1)
                  (add X2 -1)))))
```

offset   pix/sec.

  0   45,198
  1   5000
  20   4863
  100   4336

I understand that the 1109 (Dandetiger) is supposed to draw lines an
order of magnitude faster than the 1108.

Disclaimer: The above does not reflect the opinions of my employer, or
maybe even me either. In fact, it may only be a hallucination and have
no connection with any events in the real world at all. Or maybe a
monkey escaped from the zoo, broke into my office, booted my machine,
and pounded it out on the keyboard.

Why can't DRI make the GEM desktop? If you all want to send letters to DRI
giving suggestions for the "new" GEM look, that's all well and good, but
there is still plenty of room for creativity in window oriented interfaces
without stepping on someone elses toes. I see Sun Windows, Microsoft Windows,
Xerox Cedar, and Xerox Smalltalk as four different interpretations of the
desktop metaphor which look nothing like the Mac. If there is anyone lackiing
is creativity, it's DRI.

Question 1 :
Does anyone know for a *fact* (as opposed to rumor) if anyone is working
on porting os9 or some unixlike environment to the ST?

Question 2 :
There has been a *rumor* drifting about (especially among sales people)
that Atari is working on module for the ST that will snap into that side
expansion slot. The rumor continues that the module contains : 1) a full
32 bit National Semiconductor chip (NS320xx ?) that becomes the main
processor (?) and 2) the 68000 thereafter is used for i/o only???? Anyone
know if this is 1)possible and 2)if anything remotely close to this is
being worked on?

Question 3 :
Does anyone know where the '50,000+ Atari's sold' number is coming from?

Trying to pin down hype versus fact.

Huh? Visual copyright?! I doubt such a thing exists - Imagine IBM copyrighting not only their ROM code but the look (the top is a plastic rectangle with these little metal pins sticking out... :-)).

My understanding of software copyright law is that someone can produce a program with a similar visual look, and as long as no code is pirated from the first

program, no infringement exists. Otherwise Xerox should certainly sue Apple.

Anyone know if DRI employed people from the Mac development team? This was my guess on why DRI gave in.

These are my personal opinions, such as they are.

The CS is not under DMA it is triggered only when the CPU has control of the bus. This is important, considering that interfacing to a controller requires at least some non-DMA initialization/set up. You are correct in stating that the Atari port is NOT a SCSI/SASI port.

> >BE CERTAIN THE DEVICE IS SCSI, AND NOT SASI, THEY ARE NOT THE SAME!!!!!

> different from the device drivers for SCSI.

The important question here is, what kind of "Boot Rom" is installed?
Would a SASI peripheral respond correctly to SCSI commands? Once you're booted, you can use a little of both. The current ROM doesn't support either.

>>By the way, there are kits to put SCSI on the MacIntosh (Xebec I believe).
>>There are SCSI Adapter boards for most IBM compatibles (from almost anyone).
>>Apple has announced plans to incorporate SCSI into the MAC (probably Jonathan)

> >My guess is that when Peripheral manufacturers see that they can get the

Motorola was not on my previous posting of those making support chips for SCSI. Obviously, they do support it very well! Does Motorola offer a chip that would be Atari compatible in some way?

This may be closer to the truth: Someone was once describing how the Cray machines used One's complement because Seymour Cray could wire it a certain way to get a speed advantage.

Cray started at CDC, so if the above is true, it may explain the CDC architecture without having to invoke patent rights.

Speaking of patent rights, the original Mauchly/Eckert ENIAC patent, one of, if not, the longest in US history, patented Digital Logic, binary AND,ORs, adders, the works. It proved possible to circumvent, but kept lawyers busy for a decade.

Neil Harris who is the publisher of Atari Explorer gave a little
talk at the local atari users group meeting about the XE and ST
line of computers. The following are a few interesting tidbits.

Regarding the 8 bit line:

1) The new pocket size 300 baud modem is out and includes free
   time on the major information networks. Also included is
   "sophisticated" terminal software with autodial, upload&
   download. He indicated it was similar to Hometerm. The
   price given was $49.95 retail.

2) Atariwriter+ is finished and the manuals are being printed up.
   Should be available in a few weeks. He also mentioned other
   software but I can't remember now.

3) The XEM music micro has hit a few snags. Apparently they have
   been having a few problems getting working silicon on the vlsi
   amy synthesizer chip. They have contracted out the remaining
   development on the chip to another company which eventually
   plans to use it in forthcoming synthesizer products. He said
   atari retains rights to the chip and when the bugs are worked
   out may come out with a product based on it.

4) He indicated that this christmas sales season is critical to
   the future of the 8 bit line and that if it does well that
   there would be new products for the 8 bit line. He did not
   confirm or deny rumors of a christmas sales spectacular to
   clear out the large numbers of 800xl(~$49.95) computers. He
   also said that atari has a 3 1/2 inch disk drive for the
   800 series but that he didn't know whether it was a viable
   product this late in the product cycle.

Being a former commodore employee he said that he had been born again
with regards to the capability of the 800 series vs the c64.

Comments on the ST:

1) He said atari had a chance to use the amiga chip set, but turned it down. Atari felt that the amiga chip set was based on 3 year old technology for a $700 video game machine and that it could do better. He questioned the marketability of the amiga(in its price range) based on its animation capabilities in the current market. The analogy with mindset which had similar capabilities at a similar price was made.

2) The atari ST basic is done and will be shipped out to all owners that mailed in their warranty card. Also 1 copy will be shipped to dealers and user groups. The time frame for this should be a few weeks. Stwriter is also almost done and would be distributed in a week or so. Also in the works is a Stcalc which would also be distributed as a freebie. This is a stopgap measure until the wave of commercial software hits the stores.

3) He indicated that several companies were working on IBM software emulators and that also some atari engineers were looking into a hardware coprocessor off the dma port. He questioned whether people would want to use "inferior" ibm pc software relative to the user friendly interface of GEM and the speed of the 68000.

4) He said that the roms were almost done and that they should be out in the december time frame. He didn't think that the DRI settlement with Apple would have any effect but that he would check about the official company position. He indicated that atari would not be so ready to cave in to Apple regarding copyrights, etc.

5) In response to a question about the education market he said atari is interested but not ready to commit in a big way until the consumer market is taken care of. He mentioned a time frame of sometime in 1986. Several local area net are being looked into. The low cost version would address up to 255 ST's and operate through the midi ports at 31kbaud. A higher cost ethernet based version off the dma port is also being worked on.

6) Regarding the 260STD he indicated that atari would continue to use the present channels(dealers) of distribution. He didn't know whether the 260STD would be marketed in the current form or as maybe a 1meg machine.

7) He said there were several expansion boxes planned to hook up to the ST dma port. One would just have 8 slots to allow expansion cards from atari or third party manufacturers. The other one was a 32 bit machine that would also hook up to the dma port. The ST would then be used as i/o processor to handle the screen,disk, and keyboard. He

said the 32032 was basically ruled out due to performance problems. It didn't really outperform the 68000 in the ST by very much. There are 3-4 microprocessors under consideration including the 68020. The 32 bit machine would be shown no earlier than the Jan CES.

8) Atari will be attending the COMDEX and will most likely be showing a finished version of the CD rom. He said atari was having problems finding parts suppliers that would do sufficient error checking, but that these have been solved and a december time frame was mentioned for initial shipments.

9) He said that atari was basically shipping ST's as fast as it could make them and that atari would not advertise on national tv until it was sure people could walk in and buy one. He indicated that many people are interested in the machine but are waiting for the first wave of commercial software to hit before committing to buy.

10) About Byte not providing a balanced view of the ST vs the Amiga, he said that atari was partly to blame in not providing machines to byte. He says they have ST's now and that they should have a review in an upcoming issue.

I guess that's it. If atari can produce it should do very well.

I am very interested in both the 520st and the amiga.
When I see an article claiming to comtain useful information
I am naturally interested, especially when it says it is n (n>50) lines long.
What do I usually find.
Three previous articles indented one column in, with perhaps 5 lines of
original content.
If you must quote other articles, please take the trouble to edit out all the
blank lines, signatures etc. This network costs a lot of money and your just
wasting it! (I am not paying for the priviledge, but will shortly)
I am afraid netnews is like a party. There is lots of drivel being talked.
Fortunately at a party, there is so much noise that you can talk rubbish
and very few people will notice.
I should point out that there is a lot of good stuff in this news group so keep
it up. However let us accept the fact that Apple has a lot of money and can
afford to sue DR if it so desires. Next topic!!!!.

Well, I don't have to be as modest as the person from Mark Of the
Unicorn. PC-Intercomm is the finest terminal package I have used

on ANY micro-computer, and I use these programs on a day to
day basis. A 520ST coupled with a Prometheus Pro-modem (equipped with
options board) makes one of the most powerful communications
packages you can buy at any price. I have used IBM PC's with
all the popular comm programs and none of them comes near the power
or convience of PC-Intercomm. The nicest touch is the smooth
scrolling feature. To get that on an IBM you will have to spend
a lot of money for an EGA graphics adapter (probably more than the
cost of an entire 520ST system) and then you would have to wait
for some software company to write a comm program to support it.
Hats off to Mark of the Unicorn for taking an important step in
making the 520ST a serious contender in the micro market.

I want to keep this short and sweet:

1. I think it's time we stopped comparing the ST and the Amiga and
   get down to business. Both are nice machines, and this 'which is
better' discussion is tiresome. I feel sorry for those in this
newsgroups who have 400/800 machines and have to wade through all
of this.

2. I will post the source of my program to make a bootable DS/DD disk
for the ST as soon as I can upload it and provide minimal docs.

3. The TOS system calls are similar to the MS-DOS version 2.x calls.
If you have Hippo C and don't understand their terse docs, MS-DOS
documentation could fill in the blanks until ST internal docs can
be had. The developer's license agreement keeps us mum on this.

4. The developer's package has Kermit, but I don't know if is a public

domain implementation.

Too much talk already. Randy.

It seems that EA, like many other people, have learned from past association
with Jack (Of *course* it's really 64K) Tramiel. I hope the new C= management
is sufficiently intelligent that they don't just follow in Jack's footsteps.

Does anyone know how to use Cut&Paste with normal ATARI-dos files on the 800?

     -- Peter (of course the 800 is the better machine) da Silva.

No offense to SUN, they are planning improved interfaces, but I wouldn't
suggest using their "top level" as a model for anyone's window oriented
user interface. They provide reasonable tools for building your own
(but these have weird limitations and...).

I could provide specific examples but I doubt anyone would be
interested.

The point: don't bother running out to look at a SUN's user interface,
it is not at all interesting.

Has anyone who uses a C70/UNIX host
with their Atari as a terminal found a
good way to handle the conversion of
output for the smaller line size
available when using a color TV as a
monitor?

A colleague has suggested that there
may be a TERM CAP already in
existence. Alternatively, some sort
of filter might prove useful.

Does anyone use the Pocket Modem by
Digital Devices? If so, have you
found a way to use the modem with
software other than the software that
comes with the modem?

I just found out about info-atari and
may not yet be on the mailing list. I
would appreciate it if any answers are
sent directly to schaen at mitre-gw.

According to The November issue of Analog Computing magazine, there
is a bulletin board specifically for the ST computers. It is the
Sixteen-Thirty-Two Atari Network (S.T.A.N.) and it can be reached
by calling (415)-552-8924.

This information was in the middle of another article so the details
are schetchy but it contains downloadable demos, news and other information
of interest to ST owners. The programs are transfered via ST Kermit.
Someone asked if there was a Kermit for the ST. Evidently there is
but I don't know where you could get a copy and the article didn't
mention either.

Hope this helps someone.

Du to the low costs of the old 400/800 computers, I now own 2 Ataris.
I would like to know if anyone knows of references or work that discusses
the use of Ataris in multiprocessing or networking with multiprocessing
abilities.
Thanks in advance, Scott Zimmerman at zimmermn@uiowa.

In re to posting damagin reviews: I kept the most damaging stuff out, but left in what related to the 'review' someone did to the Amiga in much the same way. From the same article in _Creative_, listen:

"...Even this idle exploration was not to last. After a few short hours of poking around, my ST started acting like it had eaten too much cotton candy and was looking for the men's room. I started to get duplicate images of the Busy Bee icon all over the screen. Then, random dots started speckling the screen as if bees were really the cause of yellow rain. I knew the end was near when mushroom clouds began to appear. The more I rebooted, the faster the machine would crash, until finally I turned it on and nothing happened. Sure, I had had fun a couple of hours, but I really didn't feel as though I had gotten my money's worth."

This was from the very _latest_ issue of _Creative_. It probably was written little more than a few weeks ago.

   Trip Hawkin's letter sounds reasonable and accurate to me. It seems like
a very rational stand for a company to take. I cannot see anything "appalling"
anywhere in the letter.
   I am *very* interested in why this letter offends you. I have some guesses
but I could be wrong.

Well, I guess it's official. According to the posted TOC
of ANTIC magazine, the great new ST uses the GI-8910
sound chip.
     How could this have happened? This chip is inferior
to the original Atari 800 chip, let alone anything that
could be designed today! I have just started working with
the 8910-8913 series and know what the limitations are
(there are some good points too, but ...)
Ya know, my 8910 docs are dated 1979 or so.
     I'm just surprised that such a neat new machine
would use such an old chip.
     Now, does the ST have D-A converters and DMA
and hardware timers to play sampled audio thru them?
Because that's how you'll get any decent 4-part
music out of that box.

Regarding "Trip's" letter... It is obvious that he feels very threatened
by the ST as well he might. Unless the Amiga gets a fanatical following
it will probably not compete with the ST especially with the way the
ST has caught on in Europe.

I believe a suit over piracy of video game code was settled a while ago
with damages awarded for copyright violation. The question of ROM copy-
right was left up in the air in that decision, but the copyright the
company had on the fixed scenario "come-on" screens was upheld.

It seems to me that if Apple has copyright and or trademark registrations
on their desktop image they may be able to get damages from anyone who
copies that image, in whatever form. Whether that's a good thing probably
depends on where you sit.

There is certainly precedent for this sort of thing: the original Ritchie
compiler did things this way. If your code assumes that int promotes to long
or to (void*) on a function call it will die on more machines than just this
one.

Now why they didn't follow the VAX' precedent and make ints 32 bits, and shorts
16 bits, I don't know. Are you sure that the compiler uses 16-bit ints? Strikes
me as silly on a 68000.

Lines: 553

Here is my quick and dirty program to create double sided boot disks for
the Atari 520ST. Actually, all it does is write a properly configured
boot sector to a diskette. Once that is done, you can copy TOS and the
desk accessories over and boot from the disk.

The program can also be used to install a boot on a single sided diskette
as well. A shar archive appears below. The archive contains the sources
of the programs and a uuencoded version of the binary. [Unix users can
decode using uudecode].

Users not running UNIX will have to hand edit the files out of the archive
and if they don't have access to uudecode, install it from the sources.
That requires a developer's package.

```
-------------------------------CUT HERE-----------------------------------
: This is a shar archieve.  Extract with sh, not csh.
: The rest of this file will extract:
: README wboot.encoded wboot.c mkboot.c
echo extracting - README
sed 's/^X//' > README << '/*EOF'
XDescription of the wboot program:
X
XThis program writes a bootstrap sector on the specified disk
Xdrive.  By default, a boot for a single sided 80 track diskette
Xis written to drive A:, but wboot options permit boot blocks for
Xother disk formats to be written.  This is a quick and dirty
Xprogram, of TOS-TAKES-PARAMETERS type.  I might be fun to put in
Xthe GEM hooks, but I haven't tried this yet.
X
XThe distribution includes the following files:
X
X    readme             This file.
X    wboot.encoded      A "uuencoded" binary of the wboot program.
X    wboot.c            The C language source for wboot.ttp.
X    mkboot.c      A program to create a boot.h file.
X
XThis file is a shar archive.  If you are running Unix, you can unpacking
Xit by using it as input to sh.  If not, you can hand edit the files out of
Xthe archive by removing the sh commands in between.
X
XHow to install the binary version:
X
X    1.  After unpacking, run the wboot program through the Unix program
X    uudecode.  This will generate the binary file, wboot.ttp.
X
X    2.  Using kermit, modem, or what have you, do a binary download of the
X    program to your ST.
X
X    3.  You are ready to run, see below.
X
X
XHow to install the source version (requires developer's package):
X
X    1.  After unpacking, use kermit, modem, or whatever to download the
X    sources, wboot.c and mkboot.c.
X
X    2.  Compile mkboot.c and link the object file with gemstart, gemlib and
X    osbind.
X
X    3.  Put a disk with a bootstrap on it in drive A:.  (A copy of your TOS
X    system disk).
X
```

```
X    4.  Double click on the newly created mkboot.prg file.  You should end
X    up with a file called boot.h on the same disk as mkboot.prg.
X
X    5.  Check this file, it should have one C array, boot[], which is filled
X    with hex byte values.  That is the content of your current boot
X    block.
X
X    6.  Check the source of wboot.c to make sure when you compile it you
X    will include boot.h properly.  [You may have to add device & path
X    data].
X
X    7.  Compile the wboot.c program and link the object module with gemstart,
X    gemlib and osbind.
X
X    8.  Either install this file as a TOS-TAKES-PARAMETERS file, or change
X    the file extension to TTP (which has the same effect).
X
X    9.  You are ready to run.
X
X
XHow to run wboot:
X
X    1.  Double click on the wboot.ttp (or .prg) icon.  You should get an
X    box asking you to fill in the arguments.
X
X    2.  Supply the arguments as follows:
X
X        Use -d on the line if your diskette is double sided.
X
X        Use -4 if it is a 40 track (5 1/4 inch) diskette.  (This
X             option is not tested).
X
X        Put a: or b: on the line to indicate the drive where the
X        boot block is to be written.
X
X    If you supply no arguments, a single sided boot will be written
X    to drive A:.  For example, if you want to write a double sided
X    boot block to drive B:, the proper arguments are:
X
X                   -d b:
X
X    3.  When done, click the button to start the application.  You will
X    see a line telling you the options which were selected.
X
X    4.  You will be asked if you want to write the boot.  Type Y and your
X    selected disk will blink once as the boot sector is written.  Any
X    other response will abort the write and exit from wboot.
X
X    5.  The program loops at the point back to #4.  You can write identical
X    boots to as many diskettes as you want before exiting.
X
XNot exactly a demonstration of the best of the ST, but it gets the job done
Xand I wrote it very quickly.  Good luck.
```

```
X
X                       Randy

X    wboot              Write a bootstrap loader onto a disk
X
X    Wboot writes a bootstrap loader onto the boot sector of an
X    Atari 520ST diskette.  This is a TOS-TAKES-PARAMETERS application.
X
X    The bootstrap written to the diskette can be configured using
X    flags as follows:
X
X         -d       This diskette is formatted double-sided.
X         -4       This is a 40 track diskette (5 1/4 inch.
X                       (not tested)
X
X    The diskette drive can be also selected on the command line.  The
X    usual variants are:
X
X         -d a:         DS diskette on drive A:
X         -d b:         DS diskette on drive B:
X         a:       SS diskette on drive A:
X         b:       SS diskette on drive B:
X         (no args) Default is SS on drive A:

Huh? Visual copyright?! I doubt such a thing exists - Imagine IBM copyrighting
not only their ROM code but the look (the top is a plastic rectangle with
these
little metal pins sticking out... :-)).
My understanding of software copyright law is that someone can produce a
program
with a similar visual look, and as long as no code is pirated from the first
program, no infringement exists. Otherwise Xerox should certainly sue Apple.
Anyone know if DRI employed people from the Mac development team? This was my
guess on why DRI gave in.
These are my personal opinions, such as they are.
Kevin Kinder
ihnp4!ihlpm!kvk

And boy are they wrong! Think back a few years to old Atari's vigorous
defense of its exclusive license to Pac Man. It sued and, in those
cases where it actually came to trial, won on just this point. In
essence, they argued that it wasn't the code which made Pac Man unique,
but that the look of the maze and the moving characters and the play
action were the game. And the judge agreed that if at a distance of a
few feet one couldn't tell a Pac Man clone from the original then it was
indeed copyright infringement.

I will post my one swap copy program to net.sources
when I finish my ST Terminal program.(It'll save me a lot of typing)
I'll leave a note here when I do.

Actually, lead time on articles for magazines like Creative is on the order of two to three months. The authors complaints related to the fact that some of the first ST's out the door (around July and early August) had their chips loosened in transit. This is NOT true of current machines, at least as far as I've heard.

At least one source of kermit is the ST developer's kit from Atari.

Earlier this year, MRC was looking for a new moderator.
It seems several people have tried to get off this list by sending to him
or info-atari-request at su-score, yet were unsuccessful. Do we have
a new moderator? Is the list still run from score? Knowing this
would be nice, because I wish to be removed from the list. Would the
real info-atari moderator please stand up? (And remove me from the list?)

Is there anyone out there who could help me find a terminfo entry
for an Atari 800 and/or 800XL?

If so, please reply by mail.

Thanks in advance:

Re : all the net horror stories on the amiga and atari ...

A couple of weeks ago there was a Computer Fair (Compufair)held
in Seattle. One of the big features was that the AMIGA would be there.
The ads were plastered all over all the Compufair advertising :
Come to CompuFair and see the AMIGA!!
(pant) Over a three day span of time ... the machine never made its
appearance. Officially the information booth was told that no
Amiga was available(!) and that the US mails had done in the Commodore(??)
dealer ...rumors had it that actually two or three
Amigas were readily available but that none seem capable of staying
up. the Amiga booth incidentally was taken over by a local dealer
of Atari STs which sold out their ST inventory and people supposedly
were asking to buy the demonstrators.

(Later I also found out that likewise at a San Francisco computer fair
the AMIGA made an appearance but kept crashing so the it was pulled...
this was the week prior to the Seattle fair)

I now own an Atari ST and am pretty happy with its performance so the
question is :

    Are all the Amiga and Atari horror stories just isolated
    incidents or is there a trend ???

    Are we talking about intrinsically bad hardware design or
    just loose chips???

Good point! However, I like the object-orientation of the STAR Desktop and
wish that SOMEONE would make it available in a consumer-affordable form,
since Xerox apparently refuses to do so.

I just received this in the mail today:

NEWS RELEASE, ATARI CORP.

Date: October 11, 1985
Contact: Sam Tramiel, President, Atari Corp.

SUNNYVALE, CALIFORNIA -- In an agreement between Digital Research and Apple Computer, Digital Research has agreed to make certain superficial changes to three of its application programs: "GEM Desktop", "GEM Paint", and "GEM Draw". Contrary to reports, the agreement does not require changes to GEM or to Atari Corp.'s TOS operating system.

DRI, as part of its normal development process, has prepared enhancements to its GEM appliation products which further set it apart from the Apple Macintosh. Atari is reviewing these changes. Atari promises its software developers and customers that Atari will make no changes that will reduce the capabilities of the Atari ST system and software. Further, Atari promises that any enhancements will maintain compatibility with GEM applications software on the market and in development.

Digital Research's GEM and the applications software which uses its capabilities will continue to provide the most powerful and easy-to-use computer interface on the market. The Atari 520 ST continues to be the most powerful computer delivering these features and will continue to do so at an affordable price.

* * * * *

In an unrelated development, Atari Corp. is pleased to announce the availablility of "Atari ST Basic", the most powerful an easy-to-use version of Basic for any computer. Atari ST customers who have sent in their warrranty cards will automatically receive this new product. It

will also be made available through your nearby Atari computer dealer.

The new issue of BYTE has an a very good review of the 520ST. Skimming through a copy at the local news stand, I saw alot of phases such as, "fastest micro-floppy disk access of any home computer" and "fastest hard-disk access"... etc.

In any event, it appeared that the ST received a favorable rating from the people at BYTE. I must read the article alittle closer sometime...

>   "Do the following tests on your favorite computer, and POST the
>results. ... /* draw 8000 vectors of 200 pixels long with a skew. set by
>offset */"

OK folks. On an WCW MG-1 workstation, I got this yesterday:

Offset	Mono display	Prototype colour display
0	189,000 pixels/sec.	150,000 pixels/sec.
1	113,000	136,000
20	113,000	136,000
100	114,000	137,000

The colour software is only one day old! (For those who are interested, it's slated to be released at the end of the year). Note, there is no hardware assist for line drawing.

Summary:

(Context later, meat first.)

In the October ANALOG, Atari advertises an 830 modem for US$24.99. The "Blue Book" (a catalogue of Atari-related things (of unknown reliability)) says that this modem requires an 850 interface unit. The cheapest I have seen an 850 is about US$100.

- Is the Blue Book right?
- If so, does this mean the 830 is an ordinary RS232C-to-Bell202 modem, usable on an ordinary (non-Atari) computer or terminal?
- Is this also true of the 835 that is no longer available from Computer Mail Order (see October ANALOG ad)?

Canadian prices from CMO seem to be double US prices! And they put the charges through your charge card when they take the order, not when they ship (I got the statement with the charge already, but they say they have not yet shipped!). And they seem to have little of what interested me in their ad.

In article <775@nmtvax.UUCP> madden@nmtvax.UUCP writes:
> I really don't need a modem, so the 1030 was more than I wanted to spend.
> A few pages later was the Atari ad I was informed of--in the mail now is
> a check for the 830 Acoustic modem + cartridge. At $25, you can hardly go
> wrong.... When it arrives, I'll let everyone know how it works.

In article <1799@saber.UUCP> turner@saber.UUCP (D'arc Angel) writes:
> I was just over at the Atari store looking at the $27 modem, it looks good,
> it plugs into the serial loop (back of the disk drive)...

What is the name of "the Atari store"? What is the model number of "the $27 modem"?

>These comments are mutually exclusive.... The case was specifically for the
>visual copyright, so looking too much like the Mac was exactly what Apple
>was (deservedly) upset about. If you spend 25 man years making someone, and
>someone else borrows your design, does it in 5 many years, charges less,
>and puts you out of business, wouldn't you be upset? Business needs to be
>able to protect its R&D or R&D simply won't get done.

There is no such thing as a "visual copyright" per se. Copyright
protection can be applied to the "form" of a work (for example, the
actual shape of the icons) but offers (in its current form) little
protection for software where the algorithms and the concepts
behind the interface are the valuable commodities.

Copyright law can be semi-effective for things like ROM code (eg. Apple
vs. Franklin, Apple II ROMs) but as people such as Compaq have shown,
you can still get around it.

>> I see Apple's possiveness of "Pull Down Menus" and
>>such as a little like trying to Trademark each letter of the alphabet
>>and expecting to collect royalties.

>
>Why? If I was the first to design an algorithm and got protection for it,
>I'd expect to be able to protect it.... If I invented an alphabet, I'd sure
>want royalties for it... That is an easy statement to make, I'd love to see
>you back it up with a good reason.

The problem is that there is no effective protection for algorithms in software. Patent law expressly excludes them (unless you created special purpose hardware to implement them) and copyright law only protects their "form" (be it human readable or machine readable). That's why Compaq (in the IBM PC world) can rewrite the IBM ROM code without fear of retribution.

There is merit in what you say, however. Software designers should be able to profit from their designs. But not at the expense of unfairly limiting competition or stifling "advancement of the art". The problem is that there is a very fine line between them, one which legal people in several countries (notably Taiwan) having been trying to pin down.

>>Patent, Trademark, and Copywright laws were designed to promote creativity.
>>In fact, the current laws, as used and interpreted by the computer industry
>>are being used to stifle creativity.
>
>Can you prove that? Again, if I spend my R&D budget designing a new nifty,
>and someone else takes a copy of my nifty, redesigns it, and puts me out of
>business, how in the hell was that creative? That is what apple is trying
>to prevent -- if they wrote GEM to be better than Mac, fine -- but if all
>they did was take what Mac developed and carry it across, that is frankly
>illegal.

Apple is proving it for us. Granted Apple was responsible for some neat innovations (like the Quickdraw ROMs), and *appearance* of some of the icons, etc. But consider that:

1. It has all been done before.
2. GEM is similiar but is not (by any means) a complete ripoff of the Mac.

As far designing niftys goes, if someone can redesign your nifty (which includes porting to radically differing architectures, supporting varying hardware devices, etc, writing *all* code from scratch) and put you out of business, that's life. Don't expect everyone else to sit still while you rest on your laurels. It is your business and you have a responsibility (to yourself) to continue to innovate and keep the "nifty redesigners" off-balance (BTW, this is in the first person because the original posting was, nothing personal :-). This is essentially what Visicorp *did not* do and why 1-2-3 is really the only spreadsheet you hear about now.

>If GEM had set up an agreement with Apple, they wouldn't be IN this
>position. They just took.

Personally, I don't think DRI *took* anything they didn't have a right to. But despite the moralistic/quasi-legal argument I have presented,

the unfortunate business facts are probably, that if the case had gone to court, it was a no-win for DRI:

1. While in court, DRI probably would been prevented from marketing GEM (even if eventual decision in their favour).
2. Apple probably threatened never to send any work to DRI again and DRI's performance hasn't been earth shattering lately.
3. The publicity would not have helped.
4. Court costs would have been sustantial.
5. DRI might have lost after all.

Apple is not a villain. They are a business trying to protect their interests and this time they got away with scare tactics. But Apple is no saint either.

The opinions expressed in this article are those of an interested layman and as such, are probably only have a curiosity value. They certainly don't reflect the opinions of my employer.

*** REPLACE THIS LINE WITH YOUR MESSAGE *** (WHY??)

I would question anyone who would call the Mac Object Oriented in it's
standard configuration. I would pay money to see anyone who can dynamically
link conpiled functionality into their programing environment on the Apple
Mac in this configuration. You can purchase a Small-Talk subset for the
mac (could this be your angle?).

         Signed Questionable??

>I feel sorry for those in this
>newsgroups who have 400/800 machines and have to wade through all
>of this.

I own an 8-bit ATARI and use it regularly. Many of you know me from my various comments and uploading the Table of Contents from ANTIC magazine every month.

Even so, I hope to own an ST some day (probably the 260STD) so I am greatful for all the information that is posted here every day on the ST line of computers. Especially am I greatful to the few that upload information from CompuServe and other BBS's with information that we might not see for months if at all.

Don't assume we don't appreciate this if we own an 8-bit computer. I mean this an no flame to the poster since I know he meant well. Please, if the information is primarily for the ST, so state in the subject line as I try to do. That allows others to skip over them if they have no interest. In short, I was beginning to worry about this newsgroup until the release of the ST computers. I'm just glad to see it so active even if few of the articles are specifically for the 8-bit machines. Happy computing...

"In fact, the matrix on the 1200XL keyboard is the same as for the 400.

Adapting it for the 400 requires removing the 2 ICs on the board and soldering jumpers from the (now) empty holes to the keyboard socket in the 400. One can figure out how to do this by reverse engineering the membrane keyboard or via the Tech. Ref. Manual."

I went out and bought one of these keyboards (they look quite nice, and only $4.95!), but I don't have a TR Manual. Does anyone have the information I need to make the connections? Thanks.

A month ago, I asked for details about what a disk looks like to an Atari 600xl computer. Here are some things I have learned since then.

The Atari 800 series does indeed talk to its peripherals at 19.2K on an asynch serial line. The levels are TTL, not RS232C.

On SIG/M disk 171, there is a file "ATARIBUS.LBR". This is a collection of programs that make a CP/M-80 machine look like several Atari disk drives. SIG/M is the major publisher of public-domain CP/M programs; their disks are widly available, often from "RCP/M" systems (lists of RCP/M systems pass through usenet frequently). The ataribus system is written in BDS C. Source and (patchable) binaries are provided. And instructions on how to use it.

The ataribus documentation suggests dealing with the TTL level problem by bypassing your CP/M system's level converters (probably 1488 and 1489 chips). I don't like this, so I am going to try to build a level converter for my Atari. I am hoping that the Atari connector provides +/-12V.

A good book on copyright law is "The Copyright Book" by William S. Strong, an attorney who specializes in the field. The publisher is MIT Press. The book is a well-written, plain language explanation of copyright law and the reasons behind the law. According to Mr. Strong, the Federal copyright statute protects "original works of authorship fixed in any tangible medium of expression, now known or later developed, from which they can be perceived, reproduced, or otherwise communicated, either directly or with the aid of a machine or a device."

There are three criteria that must be met for something to be copyrightable: fixation, originality, and expression. Fixation is the act of putting something in a form in which others can perceive it. To be original, a work must be the product of the mind of the author (or minds of the authors). Finally, one can only copyright an expression of an idea, and not the idea itself.

This all sounds simple enough, but it's not. There is the idea of a derivative work, which is one in which someone else's work is "recast, transformed, or adapted". According to Strong, "When a derivative work gets its own copyright, this copyright is limited, like all other copyrights, to whatever material is original with the creator." But he also says that "copyright in the expression of an idea will not be enforced so as to prevent other people from putting the idea to pratical use."

I'm no lawyer, but my feeling after reading this book is that Apple might be able to patent some of the techniques they introduced in their user interfaces, but they can't copyright them. However, they can copyright particular screens and presentations. They could even copyright the order of operations that a program presents to the user. Even if DRI's interface doesn't look exactly like that of the Mac, Apple might claim that DRI's interface (screens and presentation, not the techniques involved) is derived from Apple's, and that DRI didn't get permission to copy the part of their interface that wasn't original. I haven't seen Gem or anything from Xerox PARC, but this is the only explanation I can think of from what I have heard so far. I have no idea whether Apple had to obtain copyright from Xerox to develop and market the Lisa and Macintosh systems; from what I have read, it seems that they copied a lot of the ideas but not the expressions of those ideas.

First off, BOTH machines could use the support; like the Mac hackers
say, there needs to be SOMETHING besides the IBM PC.

Second, regarding which machine is best, obviously you & AT&T have
differing opinions :-).

When we decided to buy a modem for ours 800XL, the MPP Microbits was highly recommended and difficult to acquire. When we checked further we learned that Microbits was going out of business and the manufacturer's pipe line had dryed up, - our dealer could not order one. After checking around, another Rochester dealer located several of them, at a significant price reduction.

We purchased and it worked well, plugging into the 800 XL joystick connector (#2); eventually the phone plug became disconnected from the circuit board giving me a reason to look at it more closly. Having reason to open the case, I was amazed at the lack of workmanship (the I/O connectors are glued in place, indicators are mounted on cardboard, the AC cord strain relief grommet is mounted on cardboard). Once I repaired the plug (remount, solder and glue - the manufacturer clearly missed it when glueing the I/O connectors in place). It's now back in service and works well - I have resolved to eventually relace the cardboard with something more substantial.

Chuq makes these assertions twice now...
> .... The case was specifically for the
> visual copyright, so looking too much like the Mac was exactly what Apple
> was (deservedly) upset about. If you spend 25 man years making someone, and
> someone else borrows your design, does it in 5 many years, charges less,
> and puts you out of business, wouldn't you be upset? Business needs to be
> able to protect its R&D or R&D simply won't get done.
>
1) Actually, the case was for something more ambiguous than the "visual
copyright", it was for the "look and feel" of the MAC interface.

2) Nowhere has Apple alleged that DRI "borrowed the MAC design."

3) Previously Chuq claimed that the MAC interface was 10 man years, while GEM represented 1 year. Now its 25 to 5. I personnaly don't have the actual figures, I suspect Chuq doesn't either. However, GEM is not a "rip-off" of MAC software. (It does provide a similar user interface, the software, its OS interface, and its programmers interface are all unique to GEM.)

4) Puts Apple out of business? What?

5) Apple's R&D investment is protected. MAC software is incompatible with GEM software and vice versa. GEM is not going to replace the MAC window environment. Aggresive pricing strategies by Atari and Commodore may indeed hurt Apple's low end business, as IBM has damaged their share of the high end market, but this has nothing to do with GEM.

> Why? If I was the first to design an algorithm and got protection for it,
> I'd expect to be able to protect it.... If I invented an alphabet, I'd sure
> want royalties for it... That is an easy statement to make, I'd love to see
> you back it up with a good reason.
>

Nowhere has Apple alleged that DRI has misused copyrighted algorithms.

> business, how in the hell was that creative? That is what apple is trying
> to prevent -- if they wrote GEM to be better than Mac, fine -- but if all
> they did was take what Mac developed and carry it across, that is frankly
> illegal.

Well fine, GEM is better than MAC, and, once again, while the visual interface is indeed similar, it was not a question of "take what MAC developed and carry it across", Apple doesn't claim this, and it just ain't true.

>
> NOTHING to do with what apple is doing... I wish we could keep our facts
> straight, folks, instead of these purely emotional rantings...
> --

Amen.

And now some allegory.

Copyrighting the "look and feel" of software is somewhat like trying to copyright the style and form of a book or painting. Imagine that Jackson Pollack attempted to copyright abstract expressionism, or that James Joyce copyrighted stream of consciousness in a novel. Clearly it is desireable to protect source code and executable image- the expression of the work and investment in software development- but patenting style is absurd.

Finally, the MAC interface is stylistically a direct descendant of work done by Xerox, that is in the public domain (or at least Xerox has made no effort to protect it.) And there are other related workstation windowing environments around (say on Suns and Appollos and stuff over at Bell.) Apple hasn't even a clear claim to being the originator of the "look and feel" that they are protecting.

>I believe a suit over piracy of video game code was settled a while ago
>with damages awarded for copyright violation. The question of ROM copy-
>right was left up in the air in that decision, but the copyright the
>company had on the fixed scenario "come-on" screens was upheld.

>Rick Sellens

This decision in this case was in two parts. The court ruled in favor
of the original copyright holder for the simple reason the screen acted
EXACTLY the same while waiting for some 13 year old to put in his quarter.
The space ships (or whatever they were) did the same things on both systems.

The court threw out the second part of the argument which stated the ideas
or visual images were also copyrighted because they depended on the 13
year old to make the exact same moves to duplicate the visual images.
(Ever see a kid play PAC-MAN? :-)

Opinion Warning -- My opinions follow, stop now if you have a weak stomach

In MY opinion, speaking as an engineer and NOT a lawyer, the first decision
is normal copyright law. If you make a copy of a video-tape, the visual
images are exactly the same, thus violating the copyright law. (Simple case
I know, but a program stored in rom is just like a video tape in a vcr.)

The second decision seems to favor DRI, in that the two operating systems
look alike, but not exactly. (How about all the space-firebirds rip-offs).

I think this is a simple case of a BIG computer company intimidating a
smaller company by a threatened lawsuit. (No wonder Jobs left :-)

To the contrary, visual look is under copyright - the same law that covers
photographs etc.

I once received a mailing from a British company that specialises in recording
screen displays for software houses so that there was a formal record ready
for any copyright legal action.
According to them, screen displays are easy to enforce under copyright law
than object code.

I would agree, however, that Apple have no greater case against DRI than
Xerox PARC have against Apple, Kodak, Interleaf, Xyvision, Caddex etc etc

who also use this type of screen interface.

Organization: AT&T Bell Laboratories
Lines: 61
Xref: watmath net.micro.atari:1475 net.micro.amiga:473 net.micro.mac:3123
net.micro.6809:567 net.music.synth:596 net.micro:12464

As someone who has done quite a bit of computer music synthesis
programming, I've come to believe that the sound chips built into
a home computer are ultimately irrelevant.
     By that I mean that for games and beginning music hackers,
the three or four musical parts (voices) provided will be OK.
You can do a lot with 4-part harmony, or even 3-part plus
percussion.
     But as you get serious, you find that you need
more parts than the built-in hardware and software support;
plus you want more sound qualities (timbres), and ADSR
envelopes, etc etc.
     With the exception of that MSX Yamaha Z-80 machine
with the built-in FM chips, NO computer on (or about to hit)
the market provides enough hardware/firmware up front.
Check out (and correct, please) this list:

Atari800 4 parts, some timbre control
Commo64 3 parts+percussion, "
Mac 4 parts, total timbre control (waveform tables)
Amiga like Mac, with more HW support and some patching
ST 3 parts + percussion (GI 8910, ancient, OK for games)
Apple][, IBM PC 1 part beep, no volume nor timbre -- joke city!
TRS CoCo 1 part, control of volume but not timbre (BASIC)
TRS CoCo 4-8 parts, total timbre control (like Mac, Amiga)
TRS CoCo 1-2 parts, FM synthesis with ADSR

Okay, I listed my trusty Coco 3 times for a reason.
It has a built-in D-A converter that outputs to your TV
any sound you can conceive and compute fast enuf.
The built-in BASIC does only one square wave with volume control.
But my own software, and some commercial packages,
support 4 parts with user-defined waveforms much like
a super Hammond organ. I can easily extend mine to 6-8 parts
by accepting a lower sampling rate.
And I have written an FM synth that I play from the keys
and can "bend" the timbre and volume within a note with
the joystick.
So--does "the Coco have FM?" Does "the Coco have
8 parts, infinite timbres?" Well, it has a D-A and some hackers
willing to write some tight assembler code.
The Mac, Amiga, and ST are all believed to contain
8-bit D-As. Use whatever built-in hardware (DMA, etc) to help
you write code, and you too can sound as good as a Coco. Better!

But software synthesis can go only so far.
Now you must ask "what kind of peripheral synth'ers can I buy/build
to plug into my computer?" Apple][has the Mockingboard
and Syntauri; Coco has Symphony-12; etc. Did Apple really do
musicians a favor by putting almost nothing in the][series?
Still not satisfied? Get a MIDI interface
(all new machines and the Coco have these available, cheap).
Then the sky's the limit -- or should I say your wallet?

To summarize -- built-in music chips are like the built-in
RAM and disk drive -- no matter how good they are, you'll
want to add more. But, unlike existing RAM and disks, the music
chips will probably sit unused once you upgrade.
So why not just ignore the built-in music chips in
the first place, if the rest of the machine has what you want?

Ok, what if I wrote an exact copy of pacman and then gave it away. Would
anyone be able to sue me?

In a previous article it was mentioned that Atari has
been ignored by the press and part of the reason being that Atari
was not "giving" machines/info that they should.

I strongly disagree. I believe that we have seen two very
different ways to market a machine as shown by the Amiga
and the 520ST. Commodore went to all of this hullabalo and
general hype -- WHERE IS THE MACHINE? On the other hand,
Atari didn't say anything UNTIL THE MACHINES HAD BEEN shipped.

Speaking of Byte, look in the next few issues -- GUARANTEED an
in-depth look at the Atari 520ST. Other magazines? Compute!, Creative
Computing, Personal Computing, Family Computing,
Infoworld, Computer Shoppers...
this list goes on. Well done ol' chap!

On another note: the people who brought you "Printworks" and "Set FX+",
Robert and Mary McDowell from SoftStyle (a Honolulu based company)
came into the store today to get some software from us -- "Mudpies" and some
demos... they also have the developer's
kit and are developing software for the 520ST.

Excitement in paradise,

Aloha,

     Rather than answer what you've asked, I think it might be a good
idea to say that the best reference material on OS-9 are

Rainbow Magazine
which is specifically about the Color Computer, but often carries ads

for other OS-9 systems (including 68K systems).

68 Micro Journal
which is available from
Computer Publishing Inc.
5900 Cassandra Smith Rd.
Hixon, Tn. 37343

which is a general 680x0, 680x, Motorola chipset magazine. I think I've answered your questions elsewhere anyway. The best source of info on OS-9 is Compuserve's OS9 SIG, which is a semi-official source of the OS-9 Users' Group's public domain programs. The net.micro.6809 people have placed comments 'here' but probably are best talked to in their own group. Also, I hope to have BIX's 'os.9' conference turned into a good resource too. This'll be hard, seeing as I've only got a couple of people to call BIX so far (it's not officially open yet) whereas the Boston Computer Club seems to be full of Apple, IBM and CPM people.

I am attempting to get 2 column output with
AtariWriter and a Gemini 10X printer. I follow the
instructions in the AtariWriter manual - set
new margins - but all I get is one column. The
single column is as narrow as the first column
should be, but the second column never show up.
The correct printer driver is also loaded when I am
doing this.

Anyone out there ever get 2 columns with AtariWriter?
Any suggestions?

Thanks,

Brian Reilly

I've had a DS drive for 3 weeks (as a pallative, while waiting for the
#$%#$% hard disk). No, the sides are not referred to as seperate entities.

The only glitch I've noticed is that SS disks can't be copied onto DS
disks using the desktop copy thing. No other surprises I've encountered.

    From: nep.pgelhausen@ames-vmsb.ARPA

    A while ago I sent a msg to the net asking if anyone had any info
    on hard disk interfaces for the Atari. So far I have had no answers.
    I just had an idea, and so I have a more specific question:

       The ATR 8000 (by SWP) allows interfacing to off the shelf 5&1/4
       and 8 inch disks. Does it also allow interfacing to hard disks?
       If so, which interface? SCSI would be nice because there is a
       Bernoulli Box which uses SCSI.....

         Thanks for any info,
                  -Richard Hartman
                  max.hartman@ames-vmsb

P.S.: Does anyone know if SWP is still around & functioning?

The ATR8000 doesn't handle hard disks. However, they have a newer model
called the ATR8500 which does. I think you give up the ability to use
eight inch diskette drives.

The 520ST keyboard has its own processor that sends scan codes on a serial
link to the main processor. So I'd imagine that if you took the current
system apart and repackaged it you could get a detachable keyboard.

Not so, sorry. The Ethernet controller and the SCSI interface are on the
same board in the Sequent machines, but they are entirely independent.
The Ethernet controller is not on the SCSI bus.

Not true. Jack Tramiel talked to anyone who would listen, and promised all
sorts of dates and features which proved to be excessively optimistic.
If you need a current example (other than quality software) look at the
Atari CD ROM. Yes CD ROMs do exist, DEC sells one, no they do not sell to
end users for anything near $500, and they will not be near that price for
over a year.

[Since nobody has seen fit to create net.micro.st, and since this message is sort of in reply to messages in many places, I have cross-posted to many groups. Followups will go to net.micro.atari.]

I have seen a lot of the same misinformation passed around on the net recently, and I would like to clear up a few things. I think I speak from a position of authority as I am an ST developer, and have been working with both Atari and Digital Research.

False: The ST runs CP/M-68k.
True: The ST runs the TOS operating system (the generic name is GEMDOS), which is not at all like CP/M-68K. There were some early plans to run CP/M, but they were dropped. GEMDOS can best be described as a 68000 version of MSDOS 2.0. It has almost all the same DOS calls as MSDOS (the function numbers are even the same), except CP/M style FCB's were dropped in favor of Unix style file handles.

False: The ST hardware doesn't allow multitasking.
True: There is nothing in the ST hardware to prevent multitasking. GEMDOS is a single tasking operating system, but there are already plans to port OS/9-68K to the ST, which will give it multitasking/multiuser capability. I bet Atari is also working on a multitasking OS of their own. DRI has already shipped Concurrent DOS 68000 to OEMs. In other words, it won't be long until the ST will multitask. I personally don't view this as a very important ability for most users, but I have already posted articles on that view and won't go into it here.

False: The Amiga hardware has special provision for multitasking.
True: The Amiga is not better than the ST when it comes to hardware support for multitasking. Neither has a real MMU (the ST has a chip called "MMU", but it does not offer full protection and relocation, and was not designed for multitasking). The Amiga DOS has built-in support for multitasking, so if you must have that ability right now then the Amiga is your only choice. Of course it does cost twice as much as the

ST, so be sure you really need multitasking before buying.

False: The ST talks to hard disks at 1 megabit per second, like the Mac.
True: The ST talks to hard disks at over 1 megaBYTE per second, almost like Ethernet, and faster than an ST506 drive can deliver data. It also talks to floppies via a DMA channel, with all the work being done in hardware. The floppy controler is a standard Western Digital part which creates standard IBM format double density disks. There is no strange formatting or special drives.

False: The Amiga graphics chips offload the CPU, but the ST does everything in software like the Mac.
True: The ST has lots of custom chips, just like the Amiga.

False: The Amiga is faster than the ST.
True: The Amiga runs at a slower clock speed (7.2Mhz vs 8Mhz), and its graphics chips take over a larger percentage of bus bandwidth. In a CPU intensive task, the ST will win. I can't comment on graphics performance since I haven't had the chance to really get down and dirty with the graphics chips on either machine. It does seem that Amiga has spent a lot of time on neat looking graphics demos, while Atari has spent more time on making their OS work and on applications software. What this means is you can see lots of interesting graphics on an Amiga right now, while there isn't much yet on the ST.

False: The Amiga can run a text based shell, but the ST can only run the mouse/window oriented desktop.
True: This one is partly true. The Amiga is delivered with a text based shell (they call it the CLI), and the ST isn't. There actually is a standard shell for GEMDOS, but Atari does not provide it to end users. They used to provide it to developers, but they stopped that too. I hope they change their mind, becuase not everybody wants to deal with mice and windows. Even if Atari doesn't provide anything, there is nothing to prevent a third party from selling one. I know of one on the market already (it comes with the Haba Hippo C package), and there are at least two more on the way.

All in all, the ST is actually a very capable system at one hell of a price. The Amiga is getting a lot of good press these days, and the ST is getting very little press at all (good or bad), so many people are not taking a serious look at the machine. The people at Atari tell me this will change soon, as a number of magazines will run ST articles in the near future. Everybody should take a serious look at both machines, and at their bank balance, and decide which is best for them. I think most people will find that the ST offers the greater value for the dollar.

Thinking of writing an "LU" (CP/M Library Utility) type program for the ST?
DON'T! A friend of mine is almost finished with one that includes squeeze
and unsqueeze, and understands GEMDOS pathnames and file lengths. He hopes
that if he can come out with his program first, it can become the defacto
standard in the ST world. It would be a shame if LU were able to force its
way onto the ST, since it really lacks a lot of important features. PACK68
(the name of the new program) will be placed in the public domain with
all source code available (its written in C). Lets do something right for
a change and not let crufty old CP/M software get moved to new environments.
Please don't port LU!

*** DO NOT REPLACE THIS LINE WITH YOUR MESSAGE ***

Is it true that the Amiga only has 8 64kx4 ram chips? If
this is true than the Amiga only has 128k words of memory,
while the Atari ST has 256k words of memory. The Amiga just
became even more expensive compared to the ST. Also has any
3rd party company anounced any hardware products for the
Amiga Bus? Can you piggy back ram chips on the Amiga, like
you can on the Atari to double your memory? Also can you get a
High Resolution Monochrome monitor for the Amiga like the Atari
ST (640x400) text? I have been told that text on the Amiga is
640x200 color only. Enough questions. It looks like the ST
is a better buy if you don't care about fancy animation hardware
and you need text that is very good. Also I have herd that the
hardware on the Atari ST was designed with the Idea of IBM-PC
emulation in mind (Compatible key codes, drive/file formats,
and printer port). Also how fast are the drives (hard and floppy)
on the Amiga compared to the ST?

Brad Kummer asked how to make a DS/DD boot disk for his Atari ST. Simply
copying the files to a DS diskette doesn't work. The problem is that a
boot sector, properly set up for a DS drive, has to be written onto the
disk. The Atari BIOS provides the necessary functions, and a boot can be
written to disk with the BIOS calls in the following code fragment.

```
#include <osbind.h>
char buf[512];

Floprd(buf, 0L, SSDRV, 1, 0, 0, 1);  /* Read boot from SS drive */
Protobt(buf, 0x01000000, 3, 1);      /* Convert to DS form */
Flopwr(buf, 0L, DSDRV, 1, 0, 0, 1);  /* Write boot to DS drive */
```

where: SSDRV and DSDRV are the drive numbers of the single and
     double sided drives respectively. Drive A: is 0, and drive

B: is 1.

Unfortunately, you need the developer's kit to do this. Is there a way to do it without? Of course, once you have one copy of a DS disk with a boot on it your can clone it with image copies of the disk.

Hey, old ATARI owners, what happend to you?
Did you all get ST's or did you just give in to the pressure?
Wake up, get active, let's win this battle...
C'mon, in the whole directory there is only one note that has to do with
the old ATARI line. Let's do something about it.
To start with, has anybody had a chance to play with KYAN PASCAL yet?
The reviews in the last issue of ANTIC are pretty good, all the silly things
the language is missing can easily be simulated, etc...
Has anybody purchased the package?
What are your responces?

There is an article in the 10/1 issue of the San Jose Mecury News with the
announcement that DRI has agreed to (effective 11/15) stop supporting the
current version of GEM and to ship a modified version to avoid charges of
copyright violations of Apple's software. Apple has claimed that GEM copied
"The look and feel" or its Macintosh software and violated Apple's
copyright. GEM uses, among other things, windowns, drop-down menus, and
icons that substantially resemble the Mac.

Let us not be so hasty in judging here. It seems that competition is
good for the free enterprize system to flourish and your

"tunnel vision" and narrow-mindedness is disturbing, especially
from a software developer. Seems you would want both machines to fare
well.

Also, for such a great machine there sure seems to be quite a few problems
with it. I just thought it to be ironic that the it is so great
BUT...this, that and the other thing are wrong with it.

How come I haven't heard complaints like these from ST developers?

Aloha,
Jonathan Spangler

I realize it's only a $200 difference, but I think it's awfully slimy to

quote the monochrome price and brag about color...

Personally, I'm amazed they would even release a color display with such a strange ratio of vertical to horizontal resolution, never mind feature it in the ads. I mean, the document icons are so tall and skinny that they look more like drinking glasses than pieces of paper, and the text looks like it's all Courier Ultra Condensed. Ick. One of the hallmarks of Xerox Star (now called "Macintosh") user interface technology is the square-pixel-ratio bitmap. Hasn't anyone learned that it takes more than little pictures to make an interface easy to use?

Keywords: MIDI Hardware Addresses

I've finally received a C compiler for my ST, and now find myself in the position of still having no information about the MIDI port hardware. I bought the ST because it had the MIDI port on it... Does anyone out there have a hardware description of this? What I would like is a description of the device registers and the addresses of these registers. Also, if there is some TOS handler already in place, how do I access this?

I don't have a developers' kit, and if I order one, I won't receive it soon enough for my piece of mind, so if someone out there with this information would please pass it along to me, either by mail or posting, (mail is better, if I get responses by mail, I'll post a summary and maybe even some source code...) I'd be very appreciative.

Thanks,
Daniel Glasser

Well the bad news is that you cannot currently make a bootable? DSDD
diskette. You are stuck with using your SSDD drive as drive A, and the
big guy as drive B. Conflicting rumours abound as to Atari's intention
to remedy this situation, but the best theory is that it won't be fixed
until all of their supply of SS drives are exhausted. (Also hard drives
won't be available until they figure that everyone went for a DS drive.)

Really this ain't so bad, unless you just wanted to trash your small drive
and go for two big ones. I figure that the final configuration:
     A: SSDD
     B: DSDD
     C: HD
is a pretty good one.

I believe that you have to do the following to make a bootable DS/DD
disk.

   1) format the DS/DD disk
   2) open the DS/DD disk
   3) open the TOS disk and copy the TOS image and the decktop file
      to the DS/DD disk by dragging them to the DS/DD window.

You won't be able to make a bootable disk by using the copy utility for some
reason, but I think the above procedure will work. Happy Hacking...

Is this for real????!!!!!??? How in the world can Apple claim to have a copyright on the "look and feel" of its Macintosh software when it is such a close copy of work done at Xerox Parc?

I don't have any legal expertise, but it looks like Apple doesn't have a leg to stand on. I hope that someone with some legal knowledge will comment on this because I don't see how Apple can get away with it.

The four joystick ports are connected to two 6520 PIA (Peripheral Interface Adaptor) chips. Each bit of these ports can be set independently by software to be either an output or an input, then can be written to or read from. Specs for the 6520 can be gotten from Rockwell or Synertek. Each joystick port also contain pins for a pair of paddles. These are variable resistors. You can connect variable resistance sensors here and read them by software.
     Details are in the Atari Hardware Manual, or check old issues of Byte and other mags (around 1982, 1983).

   Old ATARI line? What old ATARI line?

>To start with, has anybody had a chance to play with KYAN PASCAL yet?

   I don't care much for pascal in any form (part of my job
is supporting a pascal compiler), but I do have a small problem
which I thought I might share with y'all, though I think I'll have
decided what to do soon anyway.
   All my woes seem to stem from the fact that I have a 1200XL. First,
I hear that the local user's group is upgrading their XL's to 512K (of
which 256K should be directly addressable, the rest being ramdisk). But
no, they don't know how to do it to a 1200XL, and don't even know if it
can be done without ripping the thing apart. So scratch that idea.
Then, I order a great little printer (tractor & friction feed, 36
different print modes (through the magic of combinatorics), 8 built-in

domestic & foreign character sets, bi-directional printing, NLQ mode,
256 user-definable down-loadable characters, etc.) and am really impressed
when it merely does a self-test. But will the 1200XL supply the interface
with the necessary current? Not a chance. Next, I hear from a faceless
net person about a nice 80-column thingee, and express interest. Guess
what? Yup, it will work with every 8-bit Atari *except* the 1200XL.
   Well, now that I wrote it all down and looked at it, it seems kinda
clear that I should get myself an 800XL before they're all gone, and
try to sell my 1200 to the user group's hardware people for spare parts.
However, if anybody has any other suggestions, at least on what interface
will drive my printer for me, I'd be willing to listen. Or if you just
want to reinforce my near-conclusion, that'd be fine too. Ah, well;
such is life.

This is the announcement by Digital Research, Inc. as it appeared on the
Compuserve GEM SIG on Oct. 1. Seems as though DRI could use some better
lawers. (Maybe Xerox should sue Apple... :-)

==========

     Apple Computer and DRI today announced that DRI will take

immediate measures to make changes to its GEM computer programs to avoid Apple's claims that the programs violate Apple's copywrights. DRI states that these changes also prepare the way for future enhancements to DRI's GEM products.

DRI agreed with Apple that is was beneficial to substantially differentiate DRI's products and avoid any possibility of infringement of Apple's copyrights.

GEM, which started shipping in April, is a portable operating system extension available for use on a number of personal computers. GEM is based on a graphics user interface which uses windows, drop-down menus and icons. DRI has licensed GEM to a number of personal computer manufacturers.

DRI also agreed to alter the style and format of its advertising and not to engage in comparative advertising with Apple products. DRI has agreed to disclaim any GEM program compatibility with Apple products and to state that GEM programs and Apple programs do not perform in the same manner.

In a signed document, DRI agreed to produce new versions of GEM, designed to be substantially different than Apple's Macintosh personal computer in both screen appearance and operation. These changes are being reviewed by Apple to insure they satisfy Apple's requirement that GEM programs no longer appear to be substantially similar to Apple's programs. The specific programs to be modifided by DRI as soon as possible are GEM Desktop, GEM Paint and GEM Draw. When the new versions are made available to DRI's OEM and retail customers, the older versions will no longer continue to be marketed. The current GEM programs will operate in the new GEM environment.

As part of a compromise and settlement, DRI has agreed to pay Apple an undiscolosed amount and to work on Apple's software development projects but denies any infringement of any Apple rights. DRI and Apple have further agreed to engage in future software developments.

I don't know that "excessively optimistic" is fair. The machine shipped
a couple of months late, which isn't too bad, and the features seem to
be in pretty good accord with the early discussions.

I don't know when/whether the Atari CD-ROM will ship, or what its delivered
price will be, but I wouldn't write it off yet. It wasn't promised
until Fall, anyway.

>:From under the bar at Callahan's: Chuq Von Rospach

Actually, I believe Apple has applied for a patent on the pull-down window approach. I don't know if the patent has been granted, and, even if it is granted, that may not guarantee the patent would hold up in court.

If DRI has agreed to change GEM, it was probably to avoid a costly court fight. Apple is cash rich, and DRI is not.

If Apple succeeds here, how about all the other standalone programs which now use pull-down windows? How about regular menus (a listing of current options, enter a number to select an option) --- I'd like to apply for the patent on that.

On a related note, a company has a new word processor which automatically completes words as you enter them. (e.g, you type in 'comple' and the program adds 'te'). The company has applied for a patent on their revolutionary application of AI.

There has been a fair amount of discussion about the relative merits of the Amiga, ST520, and the Mac. However, little of it has covered what I consider to be a fundmental issue - user interface consistency.

One of the most important aspects of the Macintosh is the predictable nature of the user interface presented by applications. I own almost all of the Microsoft products (Multiplan, Chart, Word, File, and as of yesterday Excel), MacDraw, MacProject, MacTerminal, MacPascal, Mac C 4.0 (Consulair's fine C compiler), and I have more Public Domain packages than I know what to do with. With some relatively minor exceptions they all follow the user interface guidelines that Apple established. This means that I can transfer between applications without having to learn a completely new set of commands or conventions.

I do not plan to discuss the wisdom of the user interface that Apple choose, but I do believe that this uniformity is vital. It allows me to become productive with a new piece of software in a fraction of the time that is needed on other systems.

Now coming back to the Amiga and the ST520. What will the software for these machines look like when it is available? I do not doubt that they currently offer more hardware bang for the buck than the Macintosh. I also do not fault them for having a less mature set of applications - they are, after all, much newer. However, I am concerned that they may never offer the kind of environment that the Macintosh now offers.

I see no sign of Atari or Commodore making a vigorous commitment to a uniform interface. When the Mac was released Apple provided MacWrite and MacPaint. These programs, while not perfect, provided a very good example of how the interface was meant to be done. To the best of my knowledge no such examples exist for the ST520. As the Amiga is not yet available I cannot determine what it will provide. Unfortunately,

I have heard comments attributed to the Amiga designers indicating that
they are not in favor of a standard user interface.

On the basis of the reasoning above I continue to recommend that friends
buy the Macintosh rather than the ST520 or the Amiga. Comments from
other users of the net would be welcome.

Sorry for the cross posting, but it seemed necessary to reach those who
might be interested. I have included a Followup-To line directing
discussion to net.micro, as this appears to be the correct place for
general discussion of the issues I have raised.

    One of the hallmarks of Xerox Star (now called "Macintosh")
    user interface technology is the square-pixel-ratio bitmap.
    Hasn't anyone learned that it takes more than little pictures
    to make an interface easy to use?

Sure, have you seen the successor to the Star from Xerox? Its called
Viewpoint and is a complete rewrite of the Star software. Its really
amazing! Kind of like a grown up Mac interface.

Someone said that DRI was changing GEM due to Apple making a fuss
over the "look & feel" of it coming from the MacIntosh. Anyone
know HOW they are going to change it?

Will this suit(?) affect the "Intuition" shell that Commodore
is using for the Amiga?

     Unfortunately, NTSC video would give the Amiga resoulution about the
same quality as a Commodore 64, or an Atari 800, not an effective strategy.
Besides, vidio of a tv screen is very difficult to do well.

>
> I couldn't agree more. Why do computer marketing people treat us like
> the idiots like THEY are. What do they think? That we won't understand
> computer graphics?
> but the LEAST they could do is explain what the computer was meant to do.

The ad was tacky, typical of the "Marketing Hype" around this machine
(it's good, just 'hyped' too much). Unfortunately, marketing types
tend to try to market computers like "Perfume".

They just don't know how to express the "Benefits" of a personal computer.

> They want to know facts and why its better than brand x.

Engineers and MIS directors want to know why 'X' is better than 'Y',
My wife can't even figure out what 'Y' does, and she controlls the
checkbook. Sell her, and I get a computer, maybe two!

> Heck even CAR commercials understand the importance of at
> least demoing the product so that people can get a rough idea of what it
> does and looks like.
>

Did you notice the IBM commercial with the various "vehicles" going
across the crosswalk? The Amiga was the "Power" car, made to look
rediculous, but almost defeating their purpose (Sell IBM's).

An even better tactic would have been to so someone "waiting for the
IBM" and contrast it to the Amiga's multitasking. The Amiga
performance next to an ST isn't that impressive, but the multitasking
is.

Subject: More ST vs Amiga info......
Status: R

     Here's a note I came across yesterday that you all might be
interested in reading. It sums up some of the thoughts an Amiga/ST developer
has about the Amiga vs ST comparison question.
     The one question should be if the ST is that good (and I feel it is)
why isn't the Computer media/trade mags. falling all over it. What's going
on!!
     By the way I have had an ST for about 2-3 weeks,and I think it's one
of the best bargains to come along in a long time.....
     Once again I would appreciate someone posting this to micro.net.atari,
since I'am still having problems posting notes.
                              Thank You
                              Mike Boiko

From: JOHN DEMAR
Subj: st

MICHAEL:
   I'm sure you are a sane, rational person, so I'll continue...
I'm a software/hardware developer and an electronics engineer. I've seen

and used computers from $50 to $5Million and have designed VLSI chips for 6 years at GE until starting my business last year. So, the following is said from technical expertise and not first-impression judgments from marketing "fluff"...

I own (or have owned) both the Atari 520ST and Amiga PC. I've given them both a good bit of work and inspection, including o/s design and hardware architecture. Here are some facts and my conclusion:

The Amiga's graphics IC's are very powerful in their own right and the sound/io chip definitely gives nice synthesized music. But, that is where the power stops dead. However, since people respond emotionally to sight and sound, the demos are easy to catch someone's eye. Inside the Amiga, there is very little true support for the power of a 68000 cpu

In the low res mode, those fantastic graphics chips steal almost 70% (yes!) of the possible CPU time that the 68000 could be using to do real computer things like calculate, move/sort data, and plot graphics on your screen. Since the complicated screen data for the Amiga must come from the same ram on the same bus as the CPU, there are excessive wait-cycles imposed on the 68000. This, together with the CPU speed that is 10% or more slower than the Atari 520ST, the Amiga does not come close to the true power and useful capabilities of the ST.

Inside the ST, you will find MORE custom IC's than the Amiga and MORE powerful chips 'off the shelf' than the Amiga. This adds up to a real optimized, fast and versatile computer. First, there are a pair of chips working together to optimize data bus and screen data access. The memory controller prefetches 16-bit data directly for the 68000 and also places screen data onto a separate bus for the screen refresh chip. This operation only steals 8-18% of the available true CPU time.

Further into the hardware, the 520ST has three serial ports, RS-232, midi, and keyboard. All of these are handled separately from the concern of the 68000 and all in hardware. The 520ST has a 68901 interrupt controller that keeps track of 16 separate events in the system with very little intervention of the CPU (this chip is really a necessity in a true 68000 architecture and is missing in the Amiga). Now, the best feature and performer in the ST design is the custom disk DMA controller which transfers data to the RAM without using the CPU and does this at a rate of 1.3Megabytes per second! This IC also helps the Western Digital floppy controller and makes for the fastest micro computer disk access that I have ever seen. The ST brings in a 32K file in less than 4 seconds, including drive start up, directory search, etc. The Amiga takes almost 20 seconds!! Maybe you like waiting, I don't. Not to mention the optimized set-up that the DMA chip has for adding low-cost, fast peripherals like Hard drives and CD Roms. The Amiga uses

the amiga has a non-standard disk configuration and does much of the disk support in software (ie. slow). The drives have slightly more capacity than the the ST's DS drives (880K to 720K) but this is at the expense of speed. The Amiga directory format (or lack of) is done much like a commodore-64. In fact, to get a directory, the Amiga goes out and finds a program called DIR, loads it and goes back searching!

Now that I have started into the topic of software, I have more bad

news for you. Intuition is graphically and color-wise more advanced than GEM or the MAC but fails to perform as a real user interface. The windows are poorly configured and move with flicker. I rate the MAC slightly higher then GEM in usefulness but GEM on the ST is much faster and more predictable for the user. The Amiga OS(s) are full of bugs and are clumsy to use after using GEM for 3 months. As far as real software goes, the ST already has many useful programs and there are more developers working on ST projects than Amiga. (I hope plan on mostly games!)...

As a programmer, I found the 520ST documentation to be very well written and complete. And, if something was unclear, Atari was very open and very helpful. On the other hand, the Amiga has a great deal of documentation but things change everyday. Worst of all, you have to be God or Electronic Arts to talk to anyone at Commodore. They simply are not professional people.

To finish off here, I would like to say a couple of BAD things about the ST... The case could be nicer and they should have picked easier-to-find connectors for the monitor and drive ports. Besides that, I think (and over 50,000 others think) that the Atari 520ST is most powerful and elegantly configured computer ever made. Also, I feel that Atari will sell more computers than any other company has ever sold to date. This is not solely due to marketing hype (like the C-64) but from true value and power that was never offered before. Save $1000 and take a vacation next summer.... buy an ST. Sincerely, John DeMar, QMI.

I agree about showing the color monitor yet quoting the monochrome price, it's sneaky. Also one of my pet peeves is the lack of square pixels as you pointed out. I can understand not using square pixels if the screen shows text only, but once text and graphics are mixed, or for graphics only, it's a nuisance not to have square pixels.

I resently obtained a copy of the Hippo-C compiler (no floating point!!)
and experienced an error message at the linker phase that I don't
understand. I compiled one of the programs that came with the Hippo-C
using the -S switch on the link to get an A.PRG file. Once the linker
gets going it comes up with the message, "unknow segment", three times.
It then begins printing all the library function names on the screen in
the format, "redefinition of library_module". And it continues to do this
until I reboot. Is it something I said, or is this a bug in the compiler/linker?

Another infrequent occurance that has occurred to myself, and to others I
know who have the ST, is that after some usage of the TOS disk, it begins
to bring up the machine intermittently, where at times three strange little
symbols pop-up on the left hand side of the display, and then the machine
dies.   Does anyone have an idea as to what this means? Is it a bug in the
ROMs which will be remedied by the next release of the ROMs?
  Any information would be greatly appreciated...

Apple copyrighted the idea of "pull-down" menus about six months ago, i.e.
the method of moving a on-screen pointer to the top of the screen and having
the menu drop down. GEM (at least on the ST) has menus which come close to
fitting this description. I was surprised to see this kind of a patent,
also, but apparently Apple's lawyers made the claim quite solid, as can be
seen by DEC's agreement to alter GEM without a fight.

With regards to the 10Mb HardDisk, where might I obtain one???? The dealers
have no information on it, and the person I spoke with at Habba didn't
know anything about it.... Any help is greatly appreciated.

I would be curious to find out more about the IBM emulation
as I had not heard of it for the ST. Could you perhaps

enlighten us and elaborate?

SCSI is not the same as SASI. SCSI was based on SASI, but is much simpler
to integrate. SCSI is to computers what RCA Phono Plugs are to stereo.

The Atari DMA port is very close to SCSI, it provides all the critical interface signals for a "Kludge Box" which could be made by any company that wanted to do it. My guess is that Atari had a specific chip in mind, but I dont think the 5380 was the one they had in mind.

SCSI is a very high speed genaric "flexable backplane". It is capable of handling up to 8 other SCSI controllers. Each SCSI controller can control up to 8 "logical devices", including R/W disks, Tape drives, WORM drives, CD-ROM drives, Printers of various types, and even other computers. Any combination of "Initiators" (computers/pc's...) and "Targets" (peripherals) may be combined. Each "logical device" may store/address up to 4 GIGABYTES of storage. Let's see, that's 64 devices, and (best case) about 256 GIGABYTES. Did someone say the Atari wasn't expandable (like me)?

SASI uses separate Command data and DMA data busses, supports only 16 Megabytes/Logical device, and is primarilarily a "Winchester" controller only. Most SASI devices are available in SCSI, but many SCSI devices (CD-ROMS) may not be available in SASI.

The Atari Port is VERY CLOSE to SCSI, but requires a little "glue" and an interface chip, such as the NCR 5380 series chips.

To interface to the 538{5,1,0} you have to get three address lines to the address ports. Here is an example:

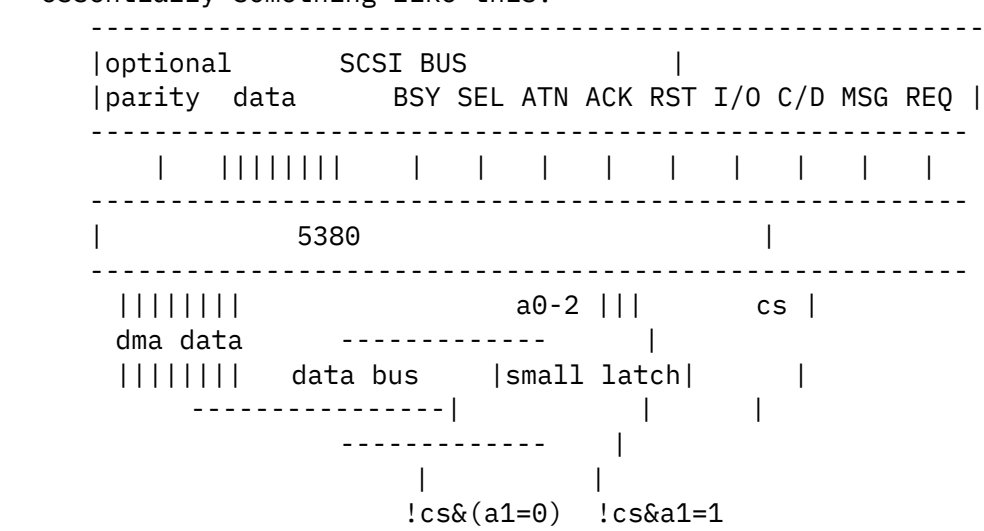
[Note: this is from an earlier article - it looks about like what Ive seen,
     but I'm not sure]

> Pin out of the ST Hard Disk Port.
>
> 1 - Data 0 2 - Data 1   Pins 11,13,15, and 17 Ground
> 3 - Data 2 4 - Data 3
> 5 - Data 4 6 - Data 5
> 7 - Data 6 8 - Data 7
>
> 10 - Interrupt Request (IRQ)
>
> 12 - Reset
>
> 14 - Acknowledge (DMA) (READY)
>
> 19 - Data Request (DMA) (DRQ)
>
> 16 - A1 (an address line)
> 9 - Chip Select - the processor (not dma) has the data/A1 bus
> 18 - Read/Write (Probably processor and DMA generated read/write signals)

     Latches can be used to get extra address lines from data
     for example:
     CS   A1   RW

```
    0    0    W    trigger address latch
    0    1    x    pass this combination to the CS on the 5380
    1    x    x    dma i/o
```

essentially something like this:



Add some software and you have instant expansion.
I am not a hardware engineer and have no idea whether this would
work, it is a guess based on documentation of the 5380 chip.

Don't go groaning too loudly about the fact that they didn't do it
"on board". They wanted to "keep the price down", a real SCSI port
has 25 twisted pair balanced lines or 25 shielded ones.

There are a few companies making SCSI interface chips which may be
even more appropriate to the ST. Here are some manufacturers:

Courtesy Mini/Micro Systems (Feb 1985, pg 125)

```
Adaptec       Advanced Micro Devices      Data Technology
Emulex        Intel                   NCR
Shugart       SMS/OMTI           Western Digital
Xebec
```

There is a good chance that at least one of these companies has a chip
that is a perfect match for the ST. Would some people try looking at
some spec sheets and post which come closest?

A more complete chart is on pg 125 of that issue.

Some good Articles include:

Mini-Micro Systems May 1984 pg 241
Mini-Micro Systems Feb 1985 pg 123

Computer Design   Nov 1983 pg 64
Electronic Design Oct 31,1984 pg 263

It is also known as ANSI PROPOSED STANDARD X3T9

BE CERTAIN THE DEVICE IS SCSI, AND NOT SASI, THEY ARE NOT THE SAME!!!!!

There are SCSI to SASI adapters available along with SCSI to just about
any standard you want. Basically all they do is demultiplex the DMA/
COMMAND channels.

I haven't seen the Habba drive yet, is there an "SCSI OUT" port on it?

By the way, there are kits to put SCSI on the MacIntosh (Xebec I believe).
There are SCSI Adapter boards for most IBM compatibles (from almost anyone).

Apple has announced plans to incorporate SCSI into the MAC (probably
Jonathan).

So if you want to be able to use an SCSI peripheral for IBM on an Atari you can.

My guess is that when Peripheral manufacturers see that they can get the
IBM, MacIntosh, Atari ST, and the Amiga market with the same product,
"SCSI compatibility" will become more important than "IBM compatibility".

Fortunately, SCSI compatibility is MUCH easier to accomplish.

Anyone who's seen a Xerox (anyone with a dandelion want to comment?) will
be the first to admit similarities, but Apple went very strongly out in
their own direction. The Mac isn't a copy of Xerox' work, it is just
influenced by it. From what the releases say, that isn't as true of the Mac
and GEM (I haven't seen GEM yet, so I won't comment on it).

I have an old 400 I bought very cheaply 2 years back. I am looking
to upgrade the RAM to 64K to use with disk software, etc., but the
cost of add-on RAM boards is as much as buying an 800XL new.

I am aware that some people have swapped the 16K chips used in the
400 for 64K parts to get the added RAM. Could anyone who's done this
give me some pointers on what's involved?

Thanks in advance.

For those of you who have seen the Antic article on using 5 1/4" floppy
drives with the 520ST, I have some interesting information. The author
of the article takes the approach of modifying the connections on an
existing 3 1/2" disk drive to get the correct signals to operate a 5 1/4"
disk drive. This, of course, voids the warranty and is quite messy in
appearance. The author takes this approach because he could not find
a 14 pin DIN connector to make the correct cable needed for the hookup.

I thought that there must be an easier way to do this, so I called my
local authorized Atari service center to ask them if they would sell
me a cable to go between my 520ST and the 3 1/2" disk drive. They said,
"Of course!" If you want to use a 5 1/4" drive with your 520ST, modifying
this cable would be the way to go. You would avoid warranty problems, and
the resulting setup would be much neater in appearance.

It is easy to put in patents and copyrights which are complete bullsh-t.
They are "valid" as long as nobody contests it. DEC still claims a patent
on the PDP-10 byte instructions even though they'd lose a real court fight
on it (and have failed to sue Xerox, Foonly, Tymshare, and Systems Concepts
for building imitation PDP-10's).

There is a difference between a patent and a copyright. What Apple apparently
has is a patent, since a copyright would not prevent anybody from recreating
from scratch software with the same functionality (consider the GNU effort).
I seriously doubt the patent would hold up against a worthy opponent. DRI
probably caved in because they want Apple as a customer.

Face it, Apple, Commodore, and Atari are glorified toy companies and behave
just like toy companies, not like vendors of professional equipment. Not a
single idea on the Mac is original with Apple.

Attached is an article from the Antic Online section in Compuserve
regarding this subject:

dgc

**** Start of attached article ****

Permission to reprint or excerpt is granted only if the following line
appears at the top of the article:

ANTIC PUBLISHING INC., COPYRIGHT 1985. REPRINTED BY PERMISSION.

** APPLE GOES AFTER GEM

* IBM DESKTOP CHANGES FORCED??

by Gary Yost and Jack Powell

10/1/85 - The San Jose Mercury News today reported that Digital Research, Inc. has agreed, under pressure from Apple Computer, Inc., to alter their GEM Desktop software.

According to the Mercury News, Apple approached DRI in June with claims that the GEM software copied the "look and feel" of the Macintosh computer software and violated Apple's visual copyright.

Digital Research, the piece goes on, "bowed" to pressure from Apple and has agreed to present a final, changed version of GEM for the IBM by November 15.

ANTIC immediately contacted Irving Rappaport, Associate General Counsel for Apple Inc., and the attorney responsible for discussions with DRI. He told us that the situation is based on visual copyrights and not on patents. "Copyright law protects features and expression, which has nothing to do with the underlying concept."

Rappaport went on to say, "We've assembled (in the Macintosh) a series of features, and what is protected is what you see on the screen. When you look at the original GEM product, you see a copy of the Mac interface."

Rappaport told ANTIC that DRI already made a number of changes and had recently provided Apple with a preliminary altered GEM. He added that Apple considered it "up to DRI to make sufficient changes" by the November 15 deadline.

He also said that the situation -- which has not gone into litigation -- was strictly between Apple and DRI. As far as Apple was concerned, it was DRI's obligation to keep Atari informed.

"It isn't a question of this feature or that feature. It's the overall appearance of the product. We're going to be looking at Microsoft's Windows and the Commodore Amiga too, and if there is a similar problem we'll address it."

Rappaport would not tell ANTIC how Apple felt about the Atari 520ST, except to say they found the nickname "Jackintosh" to be objectionable and that any use of the phrase by Atari themselves may represent a trademark infringement.

According to Michael Reichmann of Batteries Included, independent software vendors have been told by DRI to go ahead and ship products now under GEM version 1.2. But they must convert those programs to GEM 1.3 as soon as it becomes available.

ANTIC next spoke with Bill Higgs, GEM Marketing Manager at Digital Research. He told us he did not feel that DRI was infringing on Apple's copyright, but DRI's position was that they could not afford the time involved in litigation. "Given the window of opportunity for establishing DRI as a leader in interface technology, we don't want to tie up GEM in the courts for a couple of years."

Higgs went into some details of the projected changes. ...But remember, these changes currently affect ONLY the Desktop -- and ONLY the IBM Desktop at this time!

Tentatively, the IBM GEM Desktop will boot up with only two windows taking up the entire screen. There can never be more than two Desktop windows. Disk icons must be inside the windows. The "close" button has been redesigned as a rectangle and moved next to the upper right diamond button. There is no sizing of the Desktop windows and there is no trash icon -- files must be deleted from menu selection. There is also no longer any horizontal scrolling. Again, remember that so far this only applies to the IBM, not the Atari.

Higgs went on to say that DRI was moving toward a multi-tasking GEM system that would work very well with the new changes. "The basic elements of the visual interface are there. The changes are primarily cosmetic. Functionality is all there."

Higgs would not say if DRI had been in communication with Atari. Richard Frick of Atari also had no comment.

appears at the top of the article:

   ANTIC PUBLISHING INC., COPYRIGHT 1985. REPRINTED BY PERMISSION.

* EUROPEAN ST PRODUCT BONANZA

SOFTWARE GALORE COMING SOON

by GIGI BISSON, ANTIC ASSISTANT EDITOR

   No software for the ST?? Think again.

   In the September 12 issue of Popular Computing Weekly (sort of the InfoWorld of the U.K.) an article stated that "The star of this year's PC World Show -- the most exhilarating in several years -- was unquestionably Atari. They threatened to take over virtually the whole exhibition floor with well over fifty 520STs and a prototype 260ST encased in a vast glass enclosure. The new low-cost 520ST stole the show with strong software support."

   PC Weekly also stated in a separate story that "over 170 titles are being written for the ST."

   Antic Publisher James Capparell and Marketing Director Gary Yost returned from the PC World Show in London with armloads of British demo software and press kits...

UNDERSTANDING THIS SURVEY

   The software discussed in this article is in various stages of development. For each program, we will specify whether Antic has seen a FINAL Marketed version, near-final BETA Test version, earlier ALPHA Test version, incomplete DEMO segment, or PRESS Release announcement.

   Suggested prices listed this article are given in U.S. dollars when that information is available. Otherwise the prices are specified in English pounds (L) currently worth about $1.33 each. Prices are subject to change, and purchasing information for most of the following packages is not yet available, because many of the programs must be licensed by stateside companies prior to U.S. release.

** METACOMCO LANGUAGES **

Metacomco is a leading supplier of systems software for 68000-based computers. The company develops proprietary languages for computer marketers. For example, Metacomco developed AmigaDOS for Commodore International and a BASIC interpeter for Digital Research Inc.

These professional development tools are being adapted for the ST and will soon be available from the Antic Catalog. Each package includes language software, a screen editor, and a user manual. The languages come with run-time licenses and will be supported by Metacomco's technical staff via toll-free numbers.

The following languages are coming from Metacomco

ASSEMBLER/EDITOR/LINKER -- A high-specification macro assembler, originaly developed for the Amiga. Full Motorola specification and screen editor. Available October 21. $109.95. BETA.

PASCAL -- Full ISO 7185 standard Pascal compiler, already widely used on the Sinclar QL. Compiles to native code. Available in early December for $109.95. ALPHA.

LATTICE C -- Originally developed by LATTICE for 8086/88 microcomputer systems and later adapted to the Sinclair QL. This implements the original C language developed by Bell Laboratories, and follows C features and functions as described in Kernighan and Ritchies' text "The C Programming Language." Available in December for $159.95. ALPHA.

CAMBRIDGE LISP -- full mainframe implementation of the LISP development environment used in artificial intelligence research worldwide. PRESS.

IBM PC CROSS DEVELOPMENT SYSTEM -- A complete system for programmers wishing to transfer IBM PC software to the Atari, or to develop on the PC and download to the ST. Includes cross assembler, C cross compiler and linker. Scheduled for early 1986 release. PRESS.

PASCAL & MODULA

TDI Software Ltd. has FINAL versions of Modula-2 and UCSD Pascal for the ST. Both are now available at a price of L195 each, from TDI at 29 Alma Vale Road, Bristol BS8 2HL, England.

Modula-2 is the successor to Pascal as envisioned by its creator, Niclaus Wirth. It is considered to be the best language for modular programming, utilizes the GEM interface and includes a full screen editor linked to a compiler. UCSD Pascal is the industry standard used on home and multi-user micros. It includes a screen editor and utilities.

PRO FORTRAN 77

Prospero Software of London offers an ANSI Standard Fortran compiler for 16-bit 68000 microcomputers. Cost is under $300. BETA.

PC COMPILER

GST unveiled a C Compiler with a "near word-processor quality" assembly editor and linker for L59.95. Originally developed for the Sinclair QL, it includes a 73-page user manual. This is a small C without floating point, but it includes GEM bindings, making GEM development. FINAL. Also GST has a CP/M 2.2 emulator in final BETA test.

** ENTERTAINMENT SOFTWARE **

BRATTACAS

Psygnosis Ltd. calls Brattacas an "interactive video" -- the first of a generation of "electronic leisure products" for the Atari ST.

But Brattacas really is an animated graphic adventure that looks and handles like an interactive cartoon. You can use a mouse, joystick or the keyboard to control the protagonist, Kyne, as he jumps, rides elevators, duels with robots, walks smoothly -- in richly animated sequences as good as a cartoon movie.

When Kyne stumbles or falls, you even see little thought balloons like "Ouch!" Brattacas also includes a beautifully illustrated, 78-page novel to "prepare you for the world of Kyne" -- an oppressive Orwellian metropolis replete with video cameras and thought police. We have a fascinating DEMO disk of this, but it probably won't be released in the US until January, 1986.

COLOURSPACE LIGHT SYNTHESIZER

The successor to Psychedelia from a truly strange company, Llamasoft (the folks who brought Mama Llama and Sheep in Space to the Commodore 64). This program does for light what a synthesizer does for sound. An acid trip for your Atari?

As creator Jeff Minter describes it: "You can curve the screen, reflect it with hardware, interlace it, even change the resolution as the program is running. Each colour within the colour flow can be made dynamic, oscillating with a definable amplitude and frequency. By offsetting each step of the flow you get the most amazing bands of metallic fire rippling up and down the entire lightform...If you really want to burn your brains, you can kick in the stroboscopics. This is amazing in a dark room -- variable frequency slices of hi-energy photons to really freak you out."

Available for the Atari 800/XL in England now. ST version available from Antic Catalog in early 1986. BETA.

LOST KINGDOM OF ZKUL

Zkul (pronounced "skull") is an advanced adventure game. According to the manufacturer, Talent Systems of Glasgow, players should expect it to take many months to solve. The game was originally released on a miniscule 1 x 1 1/2 inch cassette for the Sinclair QL. It seems to be a J.R.R. Tolkien kind of saga -- with the usual ancient dwarves dwellings, wizards, secret treasure, etc.

The QL version of Zkul is sold for L24.95 as a package with West, a game of (what else?) notorious bank robbers in an abandoned mining town deep in Indian teritory. Events -- rattle-snakes slithering past, charging Indians -- happen in real-time outside your control. FINAL.

MISSION MOUSE

A multi-level platform game with impressive high-resolution graphics, many screens and animated sprites from Paradox Software of Essex, England. Available mid-December from Antic Catalog. DEMO.

LANDS OF HAVOC

The manufacturer, Microdeal, calls this unusual game an "arcade adventure." With 2000 screens of mazes and multitudes of characters, Lands of Havoc is very complex and very fast. Available in early November from Antic Catalog. FINAL.

MURRAY AND ME

One minute he was enjoying a lean pastrami in a deli, the next -- POW! trapped inside a 520ST. Meet Murray, a lovable born-loser kind of guy who actually likes his classy address -- after all, the rent's cheap and he has you to keep him company. Murray is the first of a new generation of ST Biotoons -- living, computerized cartoon characters who utilize the memory and graphics ability of the ST to deliver artificial personality, not artificial intelligence. Created by Israeli cartoonist Ya'akov Kirschen. Available in December from Antic Catalog for $39.95. BETA.

that matter? Mom, a hilarious Jewish mother, will nag you until you roll on the ground in fits of laughter. (You might even start eating your vegetables, who knows?) Another ST Biotoon by Ya'akov Kirschen. Available in December from Antic Catalog. $39.95. BETA.

** BUSINESS APPLICATIONS **

ATARINET MAILBOX

Software Punch of Liverpool, England is to release AtariNet, an electronic mail utility that works through the RS-232 interface and utilizes windows and icons. The AtariNet Note Editor is a text editor that allows you to write and file a message. The AtariNet MailBox lets you mail it and notifies you when a message is received. BETA.

DESK DIARY

Paradox Software is working on Desk Diary, a desk/time management system and database for the ST that features yearly memos, daily appointments, a pull down calendar, and client database. Available mid-December from Antic Catalog. BETA.

K-CALC

From Kuma is coming an easy-to-use spreadsheet calculator that utilizes GEM, mouse-driven icons and windows. It has a "wide view" zoom function, and is compatible with serial and Centronics parallel printers. It is supposed to use the ST's full RAM, and is compatible for data transfer with upcoming business packages from Kuma -- word processing, database and communications -- slated for Winter release. Available in October. L49.95. BETA.

FLEXFILE

Talent Computer Systems announced Flexfile, a database and report generator for the ST that runs under GEM. It handles mailing lists, personnel histories, credit control records, stock records, etc. It automatically keeps track of commonly used "strings" (such as names, addresses and telephone numbers). These are then formed into a menu that allows single keystroke data entry. BETA.

TIMELINK

This "Temporal Database" allows you to do almost anything with information relating to time. For example, hairdressers could keep their appointments in order, financial executives can keep track of investments, or scientists can log experimental data. See day, week, month or year at-a-glance. Calculate time between dates. Originally for Macintosh by SofTechnics of London, and soon available for the ST. $99.99. ALPHA.

RHYTHM

Rhythm is part spreadsheet, part calculator. With this combination of functions, you can do what-if analysis or use its number-crunching ability as a programmer's calculator. It also integrates with other standard GEM application programs. $49.99. BETA.

STACCOUNTS

STAccounts is an integrated, small business accounting package from Silicon Chip Ltd. that includes a sales ledger, purchase ledger, stock control and nominal ledger. All functions are written within GEM and feature mouse control and drop-down menus. A hard disk version will be available during 1986 and will support approximately 15 times more information than the 500K floppy version, according to the manufacturer. $299. ALPHA.

BOS SOFTWARE

Atari Corp. has purchased rights to offer BOS (Business Operating System) a popular British operating system. BOS may soon be bundled with the ST or available as an option. BOS National offers a complete line of business software and 40 vertical applications packages including BOS/NET, a local area network operating system. BOS software is expensive, (in the $500 range) however, and aimed primarily at the corporate market. FINAL.

Towngate Software of Dorset, England launched Cash Manager, a business accounting package that controls cash book, bank reconciliation and cash flow spreadsheet projection. It is completely integrated with BOS, and written in COBOL. Towngate is sort of the Lotus of the U.K., with software widely

distributed in 20 countries worldwide. FINAL.

** VERTICAL APPLICATIONS **

WASP

   Printers Costing is a software package for professional print shops. It will log individual job reports by client, representative and work type. As jobs are invoiced, their profit and margin are automatically calculated. Printers Costing is a member of a library of WASP specialist applications for Vets & Farmers, Legal Accounting, Insurance Brokers, and Real Estate Agents.   It runs under BOS. FINAL.

***** "I'm hungry, give me pizza, not ascii text" *****

    This is a question about what comes with the developers package: I heard that you get the source for GEM with the package, but I'm not sure if you get the sources for the underlying operating system.

    Also, is Atari (or DRI) sending updates on the opearting system and on the development system? It would be really useful since I keep hearing that there are changes to GEM coming up, and a new text editor to go with the developers system.

    Are you developers happy with the package? Does it really allow you to program? How good is Hippo C in comparison? Thank you very much,

                            Mark Galassi

<obligatory offering to line eater goes here?>

I am posting this message for Mike Boiko of Digital Equipment Corp., who is currently unable to post his own messages, due to a problem with his UUCP connection. Replies to Mike should be sent to me, I will forward them via ARPANET mail.

---------- text of forwarded message follows ----------

From: boiko%cgvax2.DEC@decwrl.ARPA (Michael Boiko MKO2-2/KO2 264-3626)
Subject: BYTE'S BW replies on Atari ST....

I too was very upset by what seemed to be BYTE magazine's lack of interest in a computer that sets all kinds of new price/performance standards for the home/office market. As I said in my conversation to Bruce, the ST is not a perfect machine, but for $799.00 retail (mono) and as low as $659 mail order (mono) it is truly an amazing deal....

For all you people who don't know, Bruce Webster writes the "According To Webster" column in BYTE magazine. Just for the record I would like to add that I do enjoy Bruce's BYTE column and there is a problem with BYTE's long "write to print" lead times not to mention vendor demo support at review time and this goes for Commodore as well as Atari....

I'am sure Bruce and I will be having many more conversations in the future, and I will try to print them here.

Well happy reading...BYTE's January review date isn't *that* far off, is it....???

There is/are comment(s) on this message.

Bruce,

Many readers on the Arpanet and USENET have been wondering why the ST has not been reviewed...and I'am one of them. What's going on this is a super machine. I've just about had it with all the hype surrounding the Amiga. I've read all about the Amiga (sound,graphics,ect ..)specs and mag. - I am not impressed by the text quality,screen flicker, system cost or present lack of availability.

Am I wrong or what we are talking about a machine that has sold over 50,000 units!!(Atari ST520 NOT Amiga)..Here's a machine that has been benchmarked by more then a few USENET subscribers at just under VAX 11/750 speed (BYTE C sieve benchmark), that comes with a rock steady 70 hz mono monitor, 1/2 MB (standard),VT100/VT220 clone keyboard,10 M/Bit DMA interface,bitblt graphics support,custom sound chips,..ect..

I couldn't help but wonder what Neil Harris and company thought of your ST remarks in the Oct issue of BYTE. The bottom line I feel is that the ST is not a perfect machine, but the remarks I have heard seem to imply that the ST is vastly inferior to the Amiga-when this is not the case.

At $799 I believe the ST must at the very minimum,mark some type of price/performance highwater mark....

Mike Boiko

ask.webster/m68000 #123, from bwebster, 1755 chars, Sat Oct 5 12:32:21 1985
This is a comment to message 110.

Mike:

the main reason the ST hasn't been reviewed is that for months Atari refused to make any machines available to BYTE, despite repeated requests. It wasn't until the August issue (cover story on the Amiga) came out that Atari suddenly changed its tune and put things into motion to get BYTE some equipment. For the last few weeks, BYTE (in the form of Jon Edwards and Phillip Robinson) has been preparing a product preview of the ST, much like the one done of the Amiga. I finally received a 520ST a few days ago; some development software is on the way, and I plan to write quite a bit about the machine. And if it makes you feel any better, in my January column (which I just sent in a week or so ago), I picked the 520ST to be the big winner of 1986 because of the price/performance combination.

The reason I wrote so much about the Amiga was because I attended the Amiga developers' conference last May and spend three days learning about the machine in detail. At that time, I was expecting to have a machine to work on within six to eight weeks. When development systems became available, I no longer had the funds to buy my own machine. However, Commodore told BYTE (in early August) that they would ship some machines to BYTE right away. Said

machines (one of which was to be forwarded to me) have never been shipped, and I find myself in the somewhat embarrassing position of having raved about a machine that I haven't worked with to any extent.
  The upshot of all this is that my opinions of the 520ST and the Amiga are becoming a bit more balanced then my earlier columns reflected. I make no apologies for my enthusiasm about the technical aspects of the Amiga, but I hope to give equal time to the 520ST.
                                                        ..bruce..

You know it's interesting to read net.micro.amiga just for a few
laughs. It seems that everyone who writes in has some kind
of problem: either a disk didn't come with the machine
(can you imagine the store that only had ONE demo and couldn't even
make a copy?), or they can't even compile the "hello world" in C, or
they can't get the speakers to work, or the machine crashed 7 times in
the matter of a few hours.

Do we hear the same kinds of things going on here? Nope...I rest my case.

Aloha from sunny Honolulu,

--

Summary:

Please advise: when attaining a new level, how is the number of hit
points added determined? Is it totally random, or does it depend on
other factors (such as how much magic apparatus you're carrying or how
many points you are over the required amount to reach that level)?

> what I consider to be a fundmental issue - user interface consistency.
> ...

I couldn't agree with you more. In fact the current 520ST master disk
already breaks with its user interface on at least two counts. The first
involves a VT52 emulator DA. Launching this DA blanks the screen and devotes
the entire machine's attention to the terminal, which looks little better
than any simple terminal program for an Apple II. Ironically, the RS232
setup program (another DA) does give a fairly resonable dialog.

Getting back to the VT52 DA, the first thing this thing does is bring up
a menu which looks something like...

1) HELP - RE232 setup
2) UNDO - Quit.

well, I tried typing 1, 2, pf1, and pf2. with no obvious effect. That is when
I noticed that the machine did have HELP and UNDO keys. So much for mnemonic
key names. Also the numbered menu items really threw me for a spin.

On one of the menus on the GEM desktop were two items - view file, and print
file. Since there was no printer on the machine, I tried the view file on
one of the random files on the master disk. The screen blanked again and I
got a weird hex dump. Well, I admitt I use FEDIT fairly regularly, but I
certainly wouldn't put it in everyone's finder! I don't this thing let you
EDIT the hex file, but this is just not stuff for non-programmers (ST buyers)
should want to see. The Mac has an elaborate print file from finder system
which basically launches the application that created the document with a
special print directive. This is really the only logical solution to what DRI
decided to provide a 'cheap' alternative that just doesn't work.

So much for first impressions!

Apple may have used a windowing system for Lisa and Mac which was pioneered
by Xerox PARC, but so have many other people. Take SUN Microsystems,
symbolics, Microsoft, AT&T, and a slew of other people creating such systems.

GEM, on the other hand, tries to emulate a MAC wondow system, not just any
window system... from the position and look of windows, including the
location of size and grow boxes, and the pattern of the racing stripes in
the title bar.

While it may be argued that Borland invented desk accessories with SideKick,
it was Apple who built them into the system as a separate entity. DRI took
the idea practically verbatim from the Mac replacing the Apple sysmbol by
the work "Desk"

Other menus as well have VERY close Mac counterparts. Oh yes, things are slightly different, but they are VERY similar.

I hate to bring up the old issue of pull-down menus, but I think that Apple lawyers missed the boat when they pattented these menus. THeir main innovation comes from the fact that these menus are decleared and defined when the program is LAUNCHED, not when the user clicks in a particular area, or pushes one of the mouse buttons. This changes the entire structure of the program as far as menu definition code is concerned. More importantly the menu bar sets a standard for where menus should be found and lets the first time user of a program quickly discover the general range of features available from within the application.

This sort of thing happened a few years ago with the arcade games vs home computer imitations that were not licensed with the original creators. The general outcome was that computer software firms such as broderbund no longer make games which look or play anything like any coin operated game, but which are still 'arcade' style games.

I haven't seen any of the recent Xerox workstations (I used the Alto a
little), but I figured this was the case. Xerox introduced (or at least
popularized) the mouse and icons, but the detailed approaches are quite
different. I believe that their interface was based primarily on
dragging icons to other icons, which only survives in the Finder as the
Trash and copying files -- in Xerox systems, one would print a file by
dragging it to the printer icon, and I think one would invoke a program
on a file by dragging the file to the program's icon (I think the
printer and trash can were just particular cases of this general
facility).

I have used GEM a little, and it is a very close copy of the Mac. The
standard desktop icons are in the same places (disk icons in top right,
trash can in bottom right), the standard menus are almost identical, and
window manipulation is the same (GEM added a minor extension: a "grow to
full screen" icon in the top right corner of windows). According to an
article in Macworld by one of the Lisa developers, pull-down menus and
double-clicking to open objects were innovations of the Lisa team, and
GEM copied these exactly. Anyone who knows how to use the Mac Finder
can sit down and feel perfectly comfortable with Gem Desktop; I doubt
that the same could be said about the Dandelion.

Sorry, but you CAN use the double sided drive as drive A. The only restriction
is that your boot disk must be formatted single sided.

Would anyone with a developer's package be kind enough to answer
a few ST questions?
#1 I have the Hippo C compiler. It supports numerous GEMDOS functions
of which I would like some information on. What does the function call
'create(name,attr)' do??? I assume 'attr' means attributes. Would someone
please explain the various attributes?

#2 What does the GEMDOS function 'open(name,mode)' do??? What are the various
modes???

#3 What is a 'handle'??

If any of the above questions insult anyone's intelligence, I apologize.
However, since I am a new ST owner without a development package, I
 am struggling to understand the GEMDOS functions.

**** Flame on ****

I think documentation that describes the ST GEMDOS functions should be
supplied with the computer. I shouldn't have to pay $300.00 to learn
about the DOS that my machine runs.
**** Flame off ****

Thanks in advance for any help given.

the answer to the question of resolution is right there before your weak
eyes, (hint! check the res in col 2) now as to why IBM chose that res is a
good question. As to how pretty the pictures are, i dont care if they look
like soda straws just so they function properly, keep your eyes on the donut
not the hole etc.

i may be confused but i thought the "out" was that Apple used pop-up menus
and DRI used pull-down. am i wrong ? is there a diff ?

I'm sure that Jeff knows that GEM is made by DRI, not by DEC.
(E-I-E-I-O, or something.... Don't you love alphabet soup?).

I'm not tremendously surprised -- there were a number of lawsuits
over PAC-MAN* several years ago, alleging that the maze/muncher/powerdots
layout was copyrightable. The owners of PAC-Man were winning them
(largely thru out of court settlements), right up till the bottom
dropped out of the home video game market.

* Disclaimer: PAC-MAN is a trademark of someone or other, who
probably has a lawyer on my trail even now....

I would like to correct some misnomers presented in the following article
concerning the relationships of the so called "FASI" and SASI/SCSI
interfaces.

>This came up in net.atari but affects ALL micro-computer owners, no
>matter what brand.
>
>>
>> Is the ST port really SASI? (Are we talking similar or are we talking
>   ^^^^
>> identical) In otherwords can I use a industry standard SASI controller
>> and Disk? This would be great.
>> --
>> --
>>   Erik James Freed
>>   Aurora Systems
>>   San Francisco, CA
>>   {dual,ptsfa}!aum!freed
>

The ST port is not SASI/SCSI compatible so one can not buy an industry standard SASI/SCSI product and directly attatch it to the Atari port, however it appears that a host adaptor can be built off the port that will let the Atari talk SASI/SCSI. Ofcourse somebody will have to write device drivers for the Atari operating system.

>SCSI is not the same as SASI. SCSI was based on SASI, but is much simpler
>to integrate. SCSI is to computers what RCA Phono Plugs are to stereo.

While it is true SCSI is not the same as SASI there is very little difference between the two. SCSI uses the same physical data and control bus as SASI with the exception of the ATN signal added to help make SCSI multi-hostable. SASI is a defacto standard that allows one host computer to talk to upto 8 controllers while SCSI is a "soon to be" ANSI standard that allows any combination of upto 8 host computers and/or controllers to talk on the same bus. Additionally SCSI has the ability to send data synchronously up to 4 Megabytes/sec. SCSI is much more intelligent than SASI and tends to off load many of the time consuming functions (mostly disk format operations) from the host computer.

>The Atari DMA port is very close to SCSI, it provides all the critical
>interface signals for a "Kludge Box" which could be made by any company
>that wanted to do it. My guess is that Atari had a specific chip in
>mind, but I dont think the 5380 was the one they had in mind.

The Atari DMA port is just that - a DMA port - and nothing more. Its only resemblence to SASI/SCSI is the REQ/ACK handshake lines and the 8 data lines.

>SCSI is a very high speed genaric "flexable backplane". It is capable
>of handling up to 8 other SCSI controllers. Each SCSI controller can
>control up to 8 "logical devices", including R/W disks, Tape drives,
>WORM drives, CD-ROM drives, Printers of various types, and even other
>computers. Any combination of "Initiators" (computers/pc's...) and
>"Targets" (peripherals) may be combined. Each "logical device" may
>store/address up to 4 GIGABYTES of storage. Let's see, that's 64

>devices, and (best case) about 256 GIGABYTES. Did someone say the
>Atari wasn't expandable (like me)?

Basicaly true except that it is a combination of 8 host computers and/or controllers on the same bus rather than one host and 8 controllers as the above paragraph states.

>SASI uses separate Command data and DMA data busses, supports only
>16 Megabytes/Logical device, and is primarilarily a "Winchester"
>controller only. Most SASI devices are available in SCSI, but
>many SCSI devices (CD-ROMS) may not be available in SASI.

SASI has only one data bus used to transfer both commands and data. Message and status information is also transferred over the same data bus. I am hopeful that all new products, including CD-ROMs, will be SCSI compatible.

>The Atari Port is VERY CLOSE to SCSI, but requires a little "glue"
>and an interface chip, such as the NCR 5380 series chips.

I disagree. The Atari Port is nothing more than a DMA channel. The circuit shown below is a SCSI Host Adapter for the Atari. It might work.

>To interface to the 538{5,1,0} you have to get three address lines to the
>address ports. Here is an example:
>

>It is also known as ANSI PROPOSED STANDARD X3T9
>
>BE CERTAIN THE DEVICE IS SCSI, AND NOT SASI, THEY ARE NOT THE SAME!!!!!

This is not true. A SCSI controller will work as well in a SASI bus environment as will a SASI controller in a SCSI bus environment. The protocol for the physical aspect of both busses allows for this. Now it is true that the firmware aspect of SASI is different from the SCSI but only in terms of the command implementation. For example both SASI and SCSI send commands over the data bus in 6 byte command blocks (SCSI also has 10 and 12 byte command blocks which allow for a 32 bit logical block address and a 16 bit transfer length). SASI commands are designed to work on a track by track basis while SCSI is designed to work on the whole unit. For instance SASI has a format track command while SCSI has a format unit command. The basic operations such as read and write data are identical. What all this boils down to is the device drivers for SASI are slightly different from the device drivers for SCSI.

>There are SCSI to SASI adapters available along with SCSI to just about
>any standard you want. Basically all they do is demultiplex the DMA/
>COMMAND channels.

I have never seen such a device. I think you mean host to SASI/SCSI adapters such as the NCR 5380. The same device is easily implemented using a simple circuit based on parallel ports.

>I haven't seen the Habba drive yet, is there an "SCSI OUT" port on it?

I believe that in the next year you will be seeing a number of high capacity drives with SCSI imbedded on the drive - therefore removing the added cost of a controller board. I am also happy to announce Motorola is building a single-chip controller which talks SCSI on one side and ST506, ST412, ESDI Serial, and ESDI Step disk interfaces. For more information see the cover story in the OCT. 3 issue of Electronic Design.

>By the way, there are kits to put SCSI on the MacIntosh (Xebec I believe).
>There are SCSI Adapter boards for most IBM compatibles (from almost anyone).
>
>Apple has announced plans to incorporate SCSI into the MAC (probably
>Jonathan).
>
>So if you want to be able to use an SCSI peripheral for IBM on an Atari you can.
>
>My guess is that when Peripheral manufacturers see that they can get the
>IBM, MacIntosh, Atari ST, and the Amiga market with the same product,
>"SCSI compatibility" will become more important than "IBM compatibility".
>
>Fortunately, SCSI compatibility is MUCH easier to accomplish.

I agree - SCSI is a great interface and would be a boon for the types of machines listed.

I was looking at the 520ST the other day in a store, and trying to find out about software for it. My main needs would be for a text editor and a telecommunications and terminal emulation package. For the latter, I was pointed to PC Intercomm, which sells for $124.95. There was a guy there who had been using it for a while and recommended it highly (he didn't work for the store), and he said it "included" Kermit.

First question: can I get just Kermit for the 520ST (i.e., public domain, from a users' group or something)?

Second question, for those who have used PC Intercomm: What does it have beyond the Kermit protocol? Assuming Kermit is or soon will be available for free, why spend $125 for PC Intercomm?

>can sit down and feel perfectly comfortable with Gem Desktop; I doubt
>that the same could be said about the Dandelion.

   Does anybody else out there think this matter of patenting a "look and feel" is stupid? If this is actually legal and defensible, then look for lots of things happening like Sony suing Sharp (my Sharp "Lynitron" TV looks an awful lot like a Sony "Triniton", right down to the logo), etc. Or how about the originator of the standard telephone design (Bell, GTE?) suing everyone else who makes a telephone? Or what about automobiles? There seem to be quite a few different companies, foreign and domestic, making cars with that "Fiero" design.
   Also, I would think that the powers-that-be at Apple would be flattered and slightly amused at the (unofficial) "Jackintosh" label, rather than claiming it's in bad taste. I personally would feel great if my idea became something of an industry standard, especially since I don't work for IB... oops, uh, for a certain company known for bludgeoning their way to industry norms. Anyway, those people at Apple Corp. should loosen up.

Summary: apple is full of it!

The pull down menus that apple is so protective of, seem to
be direct extentions of the UCSD pascal system prompt line concept.
Actually, when you get right down to it, the mac is a blend of the
UCSD pascal system and the Xerox user interface.

If anyone has rights to this technology, it is Xerox, NOT crapple.
We all know this, I just had to say it again.

A while back I posted an article about the Atari modem advertised in
Computer Mail Order for $30.00 and asked for info. For the folks who
were wondering, here's a short overview of what all happened....

October ANALOG was mentioned; spent a few days getting a copy (Socorro
is Spanish for "One Horse Town":-), then called CMO. A nice(!) lady named
Vicki answered everything she could--the cheap modem is sold out, the 1030
has it's software on disc, and the 850 interface is not needed.

I really don't need a modem, so the 1030 was more than I wanted to spend.
A few pages later was the Atari ad I was informed of--in the mail now is
a check for the 830 Acoustic modem + cartridge. At $25, you can hardly go
wrong.... When it arrives, I'll let everyone know how it works.

MPP Microbits modem was recommended, but I couldn't find out anything
about it. Apparently it plugs in through the 4th joystick port (a problem
on the XL series, which have only 2). If anyone knows anything about it,
I'd like to here.

One final thing: could someone send me some info on controlling the modem
from software. I'd like to write a VT52 emulator with an Atari-sized window
into a full size screen.

One other final thing: CMO has some fantastic deals. I didn't buy the
modem from them, but I will send for the 410 recorder and a bunch of cartriges.

I trust most of the info above is correct, but some of it comes from seeing
which way people duck when they duck my questions. Anyone who knows otherwise,

please let me know.

Thanx for all the help,
Patrick H. Madden | "Dan said 'You're a 20-Hack', and I said 'No, I'm not a
New Mexico Tech | Hack, could you get me a DSR?' and he said 'No, you're a
Box 2244 | hack.' All I wanted was a DSR, but Dan wouldn't give it
Socorro, NM 87801 | to me. Just one DSR, and he wouldn't give it to me."

Does anybody know of any other built-in commands within COMMAND.PRG
in addition to those documented in the GEMDOS manual, namely:

    dir   type   cd   md   rd   del(era)
    ren   show   copy

I came across one that saved me a lot of hair-pulling: EXIT
This command terminates COMMAND.PRG and drops you back to the desktop
so you don't have to re-boot every time. I seems a great oversight
that they did not mention this; or did I just miss something.

It is also possible to invoke COMMAND.PRG recursively (while you're still
within COMMAND.PRG). It doesn't do anything useful but could be quite
interesting at 4 o'clock in the morning. Of course, you have to 'exit'
each one.

I am planning to purchase the 520st in the near future and have the following
question....is anyone aware of any MIDI software on the market now????
I read an article in this newsgroup a few weeks ago that mentioned a lot of

MIDI software in development for the 520st. Has anyone seen any of this software on the market??? Are there any developers out there who can give me an inside tip on some release dates for this type of software?? All reponses to this article would be greatly appreciated.
sincerely,
keith hedger - intermetrics

To all of you music software developers out there:
I am a synthesist who is sold on the 520st (as I'm sure many people are).
I see many articles from developers asking what kind of music software would musicians like to see available. Well to date we've got multi track midi sequencers, patch librarians, music text programs , etc. and they are all valuable tools to the electronic musician. However, if any of you guys really want to develop something new and (I think) popular, you should consider this. One of the most popular 'new' techonologies beingmade available to synthesists is digital sampling. Until quite recently, you couldn't touch a sampling keyboard for less than $5000.00. In the last year we've seen the advent of the Mirage, a software based keyboard sampling instrument for $1700.00 and Akai has started marketing a rack mounted,midi controlled sampler for $1000.00. Deconnilix (sic) has been marketing a software digital sampler for the Apple ii for the last couple of years, but I feel that it's cost plus the required add ons makes it too expensive.
So with the advent of the 520 with it's built in MIDI interface etc. it seems that we lose the requirement for a lot of add ons, making it a greatmachine for the developement of a digital sampling software package. If someone could develop a good sampling package that sells for $150.00-$250.00 I think that they would sell A LOT of them, and would be doing a great service to electronic musicians everywhere. I would be interested in hearing from anyone who might be interested in developing this kind of software, or anyone who knows of any software of this kind currently in developement for the 520st.

Also, maybe there are reasons why itis not feasable to write this kind of
package for the st, if so , please send me e-mail and let me know.
I'll be looking forward to hearing from all you developers out there.

>   This is a question about what comes with the developers package:
>I heard that you get the source for GEM with the package, but I'm
>not sure if you get the sources for the underlying operating system.

You do not get sources of GEM or the underlying operating system (TOS). You
do get a listing of the source of the BIOS portion of the operating system and
the boot block (bootstrap loader).

>
>   Also, is Atari (or DRI) sending updates on the opearting system

Atari says they'll send updates if you return your signed license agreement.
I haven't received one yet, but there may not have been one to send. I am
looking forward to getting the icon editor, since then we should be able to
fix those funny looking 640x200 icons.

>   Are you developers happy with the package? Does it really allow

>you to program? How good is Hippo C in comparison? Thank you very
>much,

The developers package is acceptable, but not super. It's probably CPM 68K code which has been moved to the Atari environment. Not too fast, but it does work and you can develop software with it. Portions of the library is missing (no ctype stuff for example) and some things are buggy (stdio printf can trash memory). I haven't tried the GEM calls yet, since it takes quite a while to study them. Hopefully they are much better debugged.

From what I understand, the contents of the developers package is a moving target. Those who received it earlier or later than me may have something different. I know they changed editors from Mince to MicroEmacs, and some folk have complained they don't have standard I/O.

I can't compare the developer's kit and Hippo C since I don't have the latter.

Good news and bad news:

The good news is that I do have a program which makes a bootable
double sided floppy disk for the ST.

The bad news is that I don't know how to distribute it. I can
post it to the net, but how are those folks who are running nothing
but LOGO going to download it? I really can't afford the time to
make and send diskettes for anybody who might want one. I did give a
copy to my Atari dealer (the Program Store at White Flint Mall in Rockville
Md) but that only helps those in this area.

Does anybody have a downloader written in LOGO?

In response to John Demar's comments,

*FLAME ON:
>
>   In the low res mode, those fantastic graphics chips
> steal almost 70% (yes!) of the possible CPU time that the 68000 could be
> using to do real computer things like calculate, move/sort data, and
> plot graphics on your screen.

    How does one arrive at the magic 70% time figure? Also, the 68000 in the Amiga does not draw lines, polygons or fill areas. It is done by one of the coprocessors. SO the 6800 can do "real" computer things.

>   Since the complicated screen data for the
> Amiga must come from the same ram on the same bus as the CPU, there are
> excessive wait-cycles imposed on the 68000.

    Unless the ST has some sort of dual-ported RAM, the screen data must come from the same data bus in the ST as well.

>   Inside the ST, you will find MORE custom IC's than the Amiga and MORE
> powerful chips 'off the shelf' than the Amiga. This adds up to a real
> optimized, fast and versatile computer.

         If you measure a computer's worth by the number of chips,

you might as well pick an IBM over a Mac. Perhaps the custom chips
in the AMIGA are better integrated to perform several functions in one
chip. Thus you do not need MORE chips if three can do the job.

> The ST brings in a 32K file
> in less than 4 seconds, including drive start up, directory search, etc.
> The Amiga takes almost 20 seconds!!

     That is just not true! The BYTE Basic benchmark for reading and
writting a 64k file takes 25 seconds. And this is in basic! Please check
or tell us how you arrived at these figures. The Atari may be faster in
disk accesses for some operations, but please do not misrepresent the
Amiga.

> The windows are poorly configured and move with flicker.

     They do? Not in my AMIGA.

I feel that if one is to compare the AMIGA and the ST, at least one should
have used them both. I get a feeling from the previous article that you
have only used an ST and have ignored the AMIGA. While the ATARI hardware
is glorified, we do not hear much about the inner workings of the AMIGA.
I have not used an ST, so I cannot really compare the two architectures.
The ST, however, does not have any expansion slots. All that is
available is the DMA slot which is a byte wide interface. Thus to
expand the ST requires a hardware hack. The ST does not offer an
alternative to GEM for a "real" user environment. Icons may be more user
friendly for applications, but real software development is much more
efficient given a "shell" environment.

I think the Amiga speaks for itself (no pun intended). If there is a
problem with the AMIGA (I am surprised it was never mentioned) is the
non-interlace screen resolution. The ST wins hands down with a 640 by 400
text display.

Summary:

<more line-eater stuff here>

I have seen a number of messages requesting information about the Atari ST Development Kit. I am posting the contents of a letter I recently received from Atari which details the contents of the kit. Please note that any item in square brackets is an editorial comment on my part.

ST DEVELOPMENT KIT

Atari Corp. is making available the ST Developers Package for $300.00. To receive this package, send payment to:

Richard Frick, Director S/W Development
Atari Corp.
1196 Borregas Avenue
Sunnyvale, CA 94086

Richard can be reached at (408) 745-4926
or (408) 745-4922

THE DEVELOPER'S KIT CONTAINS:

SOFTWARE

Utilities Disk [includes a command shell, Kermit, a debugger, and more]
Compiler Disk [DRI C Compiler, include files, "batch" facility - compiler is 3 pass, with some assembly required]
Linker Disk
RCS (Resource Construction Set)
MicroEMACS [seems to be just like some mainframe EMACS, also includes a tutorial and an updated Hitchhiker's Guide to the BIOS]

DOCUMENTATION

Non-Disclosure Agreement (Send back signed copies or you will not get future updates)
Screen Resolution Memo (Please follow this suggestion)
Six copies of the Software Performance Report (Bug Reports) [form]
Keyboard Scan Conversions from IBM
Introduction to GEM Programming

GEM VDI Programmers Guide, Vol. 1
GEM AES Programmers Guide, Vol. 2
GEM DOS Specification, rev. 13 May 16, 1985
Hitchhiker's Guide to the BIOS Sept. 12, 1985
Line - A Technical Reference Manual Sept. 9, 1985
Intelligent Keyboard Specification 2/26/85
BIOS Listing 7/9/85 (For Reference)
DRI "C" Language Programmer's Guide
DRI Programmer's Guide (Assembler, Linker and Debugger)
Kermit Users Guide April 5, 1985
Atari Hardware Specifications Jan. 24, 1985
Programming the DMA Channel and the 1772
MIDI address for further information
Printer Specifications (2 printers)
  SMM 804 - Dot Matrix
  SDM 124 - Daisy Wheel
Cartridge Slot Specifications
Sound Chip Specifications and Users Guide
MK68901 Specifications
ST Schematic

Although I have not had a chance to start any real software development yet, the kit has been of great value in my understanding of the computer, and in helping to uncover the minor mistakes I made during the upgrade of the memory of couple of STs. The Kermit seems to work pretty well (at least with the VAX/VMS Version of Kermit), and transfers files in reasonable speed when connected at 9600 baud (I don't know about earlier messages complaining about how slow it seemed, but it seemed pretty quick to me). Software development is almost unbearable with only one drive, but with one drive and a RAM disk it gets quite nice.

I am confused. I am hearing wildly contradictory information about the amiga and st. Just for instance

> The st has fast floppy disks and a 1.33 Mb/Sec DMA channel...The amign doesn't have DMA disks. (377@eneeval.UUCP and elsewhere)
>
> The amiga has a custom programmable DMA controller (the 'copper') and no less than 25 channels of DMA including video, disk, and audio. (BYTE article).

OK, what is true. The st definitely has DMA. Does the amiga use DMA for floppies? How fast is it?

> Running the BALL demo, with a 3-D ball rolling and bouncing, and making noise, less than 8% of the CPU is being used. (BYTE article)
>
> The amiga's video controller takes up too many cycles and the amiga's clock rate is lower. The amiga has much less horsepower for computing. (377@eneevax.UUCP)

The amiga does run at 7.8Mhz vs 8Mhz for the st. How much of the rest is true?

> The amiga OS is full of bugs. (377@eneevax.UUCP)
>
> AmigaDOS is a version of TRIPOS from Canbridge.
>
> AmigaDOS was written by Metacompco (various)

If AmigaDOS is a version of a longstanding OS, how come it is full of (presumably serious) bugs? Which rumor is true here. Furthermore, I have personally crashed TOS on the st just fooling around with it at a computer store. It took me 10 minutes before my first crash. Is the amiga getting undeservedly bad press here? Doesn't TOS ever crash? Also, a note about porting the multitasking OS9 to the ST: You will give up GEM if you port OS9 probably. It seems like it will be difficult to link GEM to OS9 and presumably difficult to duplicate its function. This means an OS9 will only be useful to hacker types (like us all I suppose).

How about some additional opinions?

Yeah. No balls, no babies. I think it's a crying shame that DRI doesn't stand up and fight -- what is it going to do to their reputation and that of GEM? Nobody will believe that's it a mature product anymore. As for Apple's reputation -- well, it's already shot anyway, this can't dirty the waters any more than the already are.

1) Pull down
2) Pop up
3) Drop down
4) None of the above
5) All of the above

*** MEANWHILE ***

Regardless of which of the above terms applies to which menus (Max vs. GEM)
I believe the specific difference is that the mac menus appear when the
mouse button is clicked while the pointer is pointing to the menu name,
whereas the GEM menus fall out whenever the pointer crosses the name, without
waiting for a click (this feature, which DRI was hoping would make it
different enough from the mac scheme, has been the subject of some grumbling
by people who lose the menus by pointing off the bottoms of them.... It's
like working w/ a tightly rolled scroll that disappears when you remove
your hand from the bottom.....but falls open at the touch of a finger...)

-Richard Hartman
max.hartman@ames-vmsb

NOTE: I have not worked w/ the GEM interface at all, and only a little
w/ the mac. The above comments are based on articles read & personal
(2nd hand) gripes.

Nf-From: iuvax!jec   Oct 8 18:07:00 1985

I did some research in the Computer Shopper (October), and here are some
interesting numbers from the ads listing 520STs for "$CALL":

Company	520ST w/COLOR	B&W
Dyscom Computers p. 178 1279 Tumbleweed NE Uniontown, OH 44685 (216) 877-1197	$770 (*) (see below)	$650 (*) (see below)
Computer Creations p. 260 P.O. Box 493 Dayton, OH 45459 (800) 824-7506	$839	$689
Lyco Computer p. 17 P.O. Box 5088 Jersey Shore, PA 17740 (800) 233-8760	$860	$679
White House Computer p. 181 P.O. Box 4025 Williamsport, PA 17701 (800) 351-3442	$870	$749
Scottsdale Systems Ltd. p. 5 617 N. Scottsdale Rd. Suite B Scottsdale, AZ 85257 (602) 941-5856	$899	$699

Explanation of (*):

Atari's warranty procedure seems to be kind of strange -- I guess they're
leaving it up to the dealer. Most dealers are including a warranty in the

quoted price, but Dyscom Computers is NOT; they're charging 5% of the purchase price for a 90-day warranty. I don't know what it covers.

All these prices include the unit, the mouse, a disk drive, and the standard O.S. software.

I asked some of these places if they sold the Developer's package ($300 from Atari), and Computer Creations said they have something called the "Development C Package" for 90. The guy on the order line doesn't know what is in it, and I'm not going to pay to find out.

DISCLAIMER: I am not affiliated with any of the companies cited here, nor with Atari or the publisher of the Computer Shopper. The prices listed here were obtained either from published material or from telephone calls to the companies listed, and are provided only as a service to interested people.

Yes it could. Look at the PAC-MAN wars a while ago. Apple is suing DRI on the
exact same grounds. They're almost certain to go after AMIGA next. I'm mad as
hell about this bovine excrement, myself. GEM isn't even anywhere near being a
good copy of the Mac desktop in function: it just looks like it. Also, UNIX
isn't protected by patent (except for set-uid bits) or copyright, but by trade-
secret protection (they reckon it's too hard to reverse engineer, I guess).

Background for net.micro.amiga-only types... DRI has been sued by apple
for using the Mac desktop. They will be going after the AMIGA next, you
can count on it.

The GEM desktop has been changed: two windows only, no resizable windows,
no trashcan, no horizontal scrollbars. Strange, since none of these things
are original with the Mac, but I guess any lobotomisation would do.

I played around with a STAR at NCC-82 here in Houston, and
I remember that, too. You also sent mail by dropping it in your
out-box. The reciever's in-box then changed from an empty-box-icon to
a full-box-icon. Very nice. I hope that when Apple gets around to suing
AMIGA or C= (depending on who they're maddest at), said company will go back
to the pop-up menus and drag-and-drop model instead of lobotimising the
AMIGA like DRI lobotomised GEM.

After playing around with the Hippo C compiler, I have figured out the
answers to two of my previously posted questions:

    #1 the GEMDOS call create(name,attr) is synonymous with the C
       system call 'creat(name,pmode)'

    #2 the GEMDOS call open(name,mode) is synonymous with the C
       system call 'open(name,rwmode)'

Hippo C also supports low level I/O (read and write). I have found the
Hippo Operating System (called HOS) to be flexible, predictable and easy
to use. It is a mini Unix shell that can be easily enhanced with your
own functions.
For ST owners with only 1 drive, I've written a utility that runs within the
HOS. It allows you to copy files with only one disk swap, instead of the
usual GEMDOS four. To date file copy size is limited to 15K bytes. I'm
trying modify the program to allow copies of files up to 50K to be copied.
If anyone is interested, I'll post the source to net.sources.

Apropos to this... could anyone post the addresses (physical) to send
impassioned pleas for intelligence and imagination in the changes to
GEM, Intuition, and so on? There was a suggestion that we test the power
of USENET by creating Cheese Triscuits. How about saving it for
something more useful: either getting Apple to back down on this new idiocy
or getting AMIGA and DRI to implement the STAR desktop instead of the
MAC desktop & give Apple the finger. The AMIGA is very close as it is.

*** REPLACE THIS LINE WITH YOUR FAVORITE COMPUTER ***

FLAME ON

I for one am getting tired of the silly comparisons of the ST and the Amiga.
Please keep the articles that say "I bought an ST and the Amiga sucks"
out of net.micro.amiga. Send them to /dev/null. If you insist on posting
them please substantiate your claims by posting algorithms that were used to
achieve your results. (If the processor is only 30% effective, why and how?)
Did you run a test with 520 ST assembly language and compare it with ABasiC?

List all the variables involved. Valid comparisons are more than welcome.

FLAME OFF

In reply to an article that was posted.

The person that had problems hooking speakers to his Amiga, had problems because he was not running software that used sound. Not because of problems with his machine or the speaker interface.

The person that could not copy a disk at the dealers could not do so because the version of Intuition he was using did not support that feature. The released version does this fine.

It is relatively easy to crash preliminary versions of the OS. I have done so many times at my local dealer. The released version that came with my developers kit has only crashed when I instructed it to :-).

My personal (hopefully non-biased) opinion of these three machines.

Apple Macintosh-
  Excellent user interface, especially among differing applications. Well thought out. Excellent machine for documentation, probably the best I have seen to date. Needs a great spread sheet program and a hard disk to become the business machine it could be. Closed architecture hurts it.

Atari 520ST-
  Superb machine in monochrome mode. Very good color graphics possibilities in color mode. Acceptable sound. Machine has yet to prove itself. As software becomes available, this machine may find a niche in the home market. The closed box approach may hurt this machine more than Atari realizes. (Do they never learn?) Excellent price for performance.

Amiga-
  Most powerful graphics/sound computer ever introduced for the low end microcomputer market. (If you do not believe it, you are biased) Has the ability to revive PC market. Arcade quality games will finally be available for the home. Is powerful enough to become a business machine, but Commodore name may kill off that market. Open architecture expands power. Price is the biggest barrier.

The price performance issue can be heavily debated over these three machines. In my opinion, they are mostly equal. The decision over what is most valuable to you is a personal one that once made will probably be a good one. I personally want the best graphics/sound available and so for me the Amiga was worth the extra money. Once you use the multitasking on a microcomputer you will never want to go back to single tasking. I made the choice that was best for me, hopefully you can make the choice that is best for you. When you do that, I am pleased for you, but please do not force me to listen to you saying that I made the wrong one. (I realize I do not have to read the articles, but I keep believing that some useful comparisons will be posted.)

P.S. Anybody interested in forming an Amiga Users Group in the Portland, OR

area please contact me via email. I have two other friends also interested.

> :From under the bar at Callahan's: Chuq Von Rospach

I find it rather hard to believe that Apple would really have a case against
DRI. Anyone who has worked with "Object Oriented" systems like the Mac,
and "Action Oriented" systems like the PC, Un*x, CP/M... knows how difficult
it is to get "Dynamic Run-time Binding" from the "Action Oriented" systems.

True, in terms of it's external appearance, the GEM interface looks very
much like the Mac interface. But things like binding (install application)

are much different. I see Apple's possiveness of "Pull Down Menus" and such as a little like trying to Trademark each letter of the alphabet and expecting to collect royalties. DRI was very cautious about avoiding anything that was declared a "Registered Trademark" by Apple. The even used different terminology. Even the "Pop out" menus on the top line are very different in usage from the Mac. GEM "pops out" the menus if the selector (arrow) even touches a word in the top line (this is a complaint for some Mac users). In fact, Creative Computing (Oct 1985) has a review of the ST which cites the differences as "Bugs".

Patent, Trademark, and Copywright laws were designed to promote creativity. In fact, the current laws, as used and interpreted by the computer industry are being used to stifle creativity.

If a playwright wants to create a script from a novelist, he gets a "royalty agreement" from the novelist. Often, patent rights are "traded" between competing companies.

If Apple has the right to sue DRI over "General Appearance", then DRI should be able to sue Apple over the "Concept" of a BIOS/BDOS, along with suing IBM/Microsoft. It's almost like declaring "open, close, read, write, seek, and flush" as trademarks. The basic terminology for these processes has become standard. Without this terminology, software engineering would be "the tower of babel".

Apple (Jobs) wanted to dictate the industry standards for this (Icons & windows) generation of computers. They succeded to a point, now they want to collect. It's a little like putting Kermit or FIDO in public domain for a few years, then expecting to collect royalties for those copies distributed as public domain.

Suppose whoever came up with the various "word processor" functionalities, used on virtually all "full screen" editors, decided it was time to "pay the piper". Erase your word processor or pay a $5000 fine.

English is a language of coined words. When a new concept is developed, we generate unique vocabulary to describe it. We could have called those cute little pictures "Hieroglyphics" instead of "Icons", but no one trademarked the word "Icon" in this context. Must we continue to try and figure out new terms for these "menus that appear from nowhere"?

There does need to be some level of "invention protection" for new software concepts, but copyrighting each of the "musical chords" of software is not the way to go about it. If we found "the lost chord" of music, could we copyright it?

If Von-Neuman or Turing had patented all of the algorythms used in modern computers, computer software development would have been shackled for twenty years.

Kay, Jobs, and the other Mac developers have given a great gift to the industry in the form of an interface with humans that does not require great effort to learn. For this, they should get a Nobel Prize or something,

but not the right to sue every Tom, Dick, and Harry that comes up with
a usable "mouse and windows" interface!

[These opinions are mine alone, and subject to change without notice]

     Rex B.

Hi,

   I was wondering if anybody has or knows where to get the source code for
   any of the AMS players out there.

   Any help would be greatly appreciated.

Thanks,
  Dave.

P.S. if anybody doesn't know...AMS is the Advanced Music System of apx
(written by Lee Actor). The AMS players sometimes go by the names of
"Composer's Jukebox" or the like.   Thanks Again.

Here is another posting for Mike Boiko of Digital Equipment Corp., who is still unable to post directly.

Well ST fans there's not much I can say about this note,(it pretty much speaks for itself) except to say that this came across our internal net the other day and I felt obligated to pass it on....

I would be very interested in any comments anyone might have concerning this note. Please post responses to net.micro.atari.

Mike Boiko

****

The following text is comprised of a letter sent to this store from a customer. Obviously Mr. McClary had written Electronic Arts about their product line for the 520ST, and got the following response. Mr. McClary attached a note to the copy of this letter sent to me that said; "Hope you will share this with your users group or upload it on BBS's and get people to write EA." Well, I found the letter quite appalling, and I am sure that the majority of the Atari community will also. So, in response to Mr. McClary's request I am sending a copy of this letter to Antic, Analog and the new Atari Corporation. I am also sending a copy of the letter I wrote Electronic Arts in response to their criticism of the ST to the same aforementioned companies in the hope that these letters will be printed for all Atari owners to read, including those who are presently unable to access Compuserve.

Electronic Arts letter reads as follows:

"September 12, 1985

Mr. J.L. McClary
3222 Clearwater Drive
Cleveland, TN 37311

Dear Mr. McClary:

Thank you for the compliments on our products and for asking about our product plans for the Atari 520ST.

Electronic Arts is in favor of industry hardware standardization. For this reason, EA is supporting the Commodore Amiga because it is the best designed, best supported, and most powerful new 16 bit computer, by a wide margin. We would like to see it become a success, and eventually and industry standard.

EA is also interested in supporting hardware systems that come from companies that can properly support our development efforts, and which have the financial resources to properly develop service and sales channels, and the marketing resources to develop and maintain a large customer base. Due to the confusion in the marketplace, it is especially important for a company to have a large advertising budget in order to educate consumers about the benefits of home computing. In EA's opinion, only Apple, Commodore and IBM are in this position in today's market, and as a result, we fully support their machines (Apple II and Macintosh, Commodore 64, 128 and Amiga, and IBM PC) and compatible machines like the Tandy 1000 and the Compaq product line. We believe all these machines represent good value in computing, and we are not swayed simply by the pricing of the Atari ST, which we believe to be misleading. For example, the Atari 520ST is touted as a 512K system, when in fact more than half the memory is used for GEM, a user-interface inferior to Macintosh's and Amiga's, both of which are stored in user ROM and not deducted from the RAM available to the user. We are familiar with the marketing practices, support, and reliability of machines built by companies operated by the current Atari management, and we are not anxious to repeat that experience.

Put simply, the Atari ST is a completely incompatible machine from a company that lacks the resources or the interest to support it fully. Ironically, the consumers most likely to buy the Atari ST are currently in Atari 800 user groups. You may not realize that the current Atari management are the same people who, while they were running Commodore helped BURY the old Atari and many of it's software developers. You also may not be aware of the fact that the designer of the Amiga is Jay Miner, who used to work at Atari and DESIGNED THE ATARI 800!

NEVERTHELESS, we are currently developing Marble Madness and Financial Cookbook for the ST, in order to learn more about the machine and it's market potential; and once we can see some sales history for those products, which will be out in early 1986, we will consider expanding our efforts if we are proven to be mistaken about everything that has been written above.

I appreciate your interest and hope that you will share my views with your users group.

Regards,

Trip Hawkins
President
Electronic Arts

When I was first learning about computers (around '68) I asked a teacher
why it was that CDC machines used 1's complement arithmetic. He replied
that IBM held hefty patents on two's complement algorithms that Control
Data did not want to pay for. I have no idea whether or not this story
is true, but, if so, it shows that Apple isn't the only one playing the
patent game.

Question : given Apple "software piracy"...that is ripping off the icon
nature of the user interface from Xerox's Star ...Can Xerox sue Apple
for copyright infringement??

Observation:
It seems the "new" Apple is trying to do legally what they cannot do
technologically (keep their share of the computer market). Given the
two year lead time the mac had on the competition it's ashame they
have squandered there time with internal bickering. Who knows maybe
when the next Apple super bowl ad comes out will get to see "the
open color mac".

On to some other questions ...
What is "portab.h" and "obind.h"?
Are these include files simply accessible to GEM Developers or can
they be acquired and used by people using Hippo C compilers?

Myself and others are interested in performing the modifications
specified in "The Quarter-Meg Atari 800XL" article as featured in
BYTE 9/85. We currently have the necessary parts on order and have
acquired the BYTEnet code.

In the interim, we are looking for any advice, tips, suggestions,
warnings, etc. from those of you having experienced these
modifications.

Among our questions are:
1) Does this mod actually work?
2) Will DOS 2.5 perform the proper bank switching?
3) Is there any applicable Public Domain software
available?
4) and lastly, HELP!!!

Your comments on this matter will be greatly appreciated!

To: Burns Fisher,<fisher@ucb-vax.berkeley.edu>

Speaking of keyboards for the 400, I noticed Radio Shack is selling a keyboard for $4.95. It looks like it came from a 600XL or 800XL - I think it even says Atari on it. Does anyone know if this would be plug compatible with the 400, or interfacable with very little effort? It has all the keycaps in the proper location - cursor control, reverse video key, reset, select, etc. and would be a pretty good deal for only 5 bucks if it worked. But I looked on the back of it and there are some IC chips mounted there (the 400 keyboard is just a set of membrane switches, there are no chips on it), so it may not be compatible.

>many points you are over the required amount to reach that level)?

Well, in AD&D, you get a die rolled according to class. Fighters are a 10-sider, so they get from 1 to 10 new HP, magic users 4-siders, thieves 6-siders, clerics get d8's, and monks get d4's. This is modified by the constitution of the character, adding new hit points per level- up to 4 per level if you're a fighter with an 18 constitution (sorry, only strength gets to be exceptional and I don't know if there are any other stats in the various rogue games- 3.6.1 doesn't have others...).

Objection, your honor. Many sites archive net.sources.* but no other groups.
Net.sources frequently gets preferential treatment by expire. Net.micro.*
gets no such privilege. Post here at your own risk.

          October 1985 ANTIC Table of Contents
          Theme: Mind Tools

Page Article

8   COMMUNICATIONS: GAMES COMPUTERS PLAY
          A discussion of the Games Computers Play graphics

bulletin board and what is available there.

14 BOOKSHELF ON LASER DISK
A discussion of the CD-ROM that will be available for the ST series of computers with Tom Rolander of Activenture. He mentioned that the encyclopedia used for the demonstration at CES was the Grolier edition and will be available at the same time as the player for about $150 to $200. Pictures will not be a part of the early editions because they are very labor intensive (text isn't) and because most pictures in encyclopedias are printed by permission and permission would have to be renegotiated for the CD version.

20 GEM COLOR CASCADE
This is the first type-in program for the ST computers. It is written in C. There is also a BASIC version for 8-bit machines.

24 FIRST ST PERFORMANCE TEST
Using Byte Magazine's 'Prime Number Benchmark', ANTIC found that the ST is twice as fast as a MAC and about 100 times faster that an 800 running BASIC.

26 ST PRODUCT NEWS
A review of 'Present the Atari ST' book by Abacus. Also news on upcoming software such as 4xFORTH by Dragon Group and TWIN (a Lotus 1-2-3 clone) by Mosaic Software that will retail for $99. Arrakis Technology is developing some Tutorials and Demo disks.

28 BANJO PICKER
Program your Atari to make sounds like an automated 5 string banjo. BASIC.

31 GAME OF THE MONTH: ALIEN ASYLUM
An implacable and intimidating arcade game. Smash the lights, avoid the contagious inmates, snatch every key and keep moving. BASIC.

32 BONUS GAME: LEMONADE
Lemonade is a well-known educational simulation that teaches children basic economic concepts. This was programmed by Bob Polaro and used to be available from APX.

36 SEE HALLEY'S COMET ON YOUR ATARI
A review of 'Space Base', 'Halley Patrol' and 'Earth Views', three educational programs available through the ANTIC Catalog.

40 A STUDENT TESTS S.A.T. SOFTWARE
A review of the Krell and HBJ SAT software from the eyes of a student that tested them.

44 YOGA BREATHING--YOUR GURU, THE ATARI
A program for use on any 8-bit Atari that allows it to be used as a meditation tool for helping you learn to relax and fight stress. BASIC.

46 GRAPH 3D
Explore the world of visual calculus and create three-dimensional graphs from mathematical functions. BASIC.

51 SOFTWARE LIBRARY
The program listings for all the type-in programs in the magazine.

72 ASSEMBLY LANGUAGE: FINE SCROLLING WORLD, PART II

Learn how to fine scroll with all the speed and power of machine language. This is the second part of a two part tutorial by Mark Andrews, author of "Atari Roots".

73 PRODUCT REVIEWS

SOFTWARE: Mychess II (Datamost)
Crusade in Europe (MicroProse Software)
BOOKS: More BASIC Betting (St. Martin's Press)

Comments: Datamost has a full two page ad promoting their new line of productivity software called KWIK-WARE! They have a word processor, spelling checker, database, telecommunications package, a desk secretary, checking account program, mailing list, graphics print package, a customized form and report generator and soon a typing tutorial and a merge program that allows them all to be used together. They are $19.95 each.

#define NUM_FUNCTIONS  13   /* number of functions */

/*
     This demo creates random vector designs.  This is accomplished by
```

```
     randomly choosing a function for each coordinate halve of the two
     points describing a vector that moves through two dimensional
     space. Both x coordinate halves cannot be the same since the design
     would simply be a collection of vertical lines. Similarly both
     y coordinate halves cannot be the same.

     The values of the functions were pre computed to have the demo
     run as fast as possible.  The program will terminate on any key
     press since it is in an endless loop.

It appears that after I run an application program, the double-click
feature to open a drive/application program is disabled (or at least
set to a very high speed, higher than I'm able to invoke it). I had
to go into the control panel and reset it to make it work again.

Has anybody else experienced this?

What about the Development Package? ATARI Germany delivers this
package only to software houses and dealers. End users dont't get
any. Is anybody out there in Net-Land who can tell me, how this
is handeled elsewhere? Could eventuelly someone buy the package
in USA for me? What about the rumor of hardware coded serial
numbers?

Saving your desktop (it's an entry in the options menu) make the installation
of an application permanent. It works by updating (and if necessary creating)
the file "desktop.inf" which the system checks on a reboot.
The purpose of installing an application is to record some information about
the type of a program (so that you can use just one filename extenstion for
all executables) and to make a link between a file and the program that
handles those files so that you can have the program start up automatically
by double clicking on the file icon.

set the click-speed, and save the desktop. Seems to work on my system.

Along the same line-
     If you hit the full screen toggle, run an application, and return,
     Gem forgets and thinks you are just a large window. (i.e. the full
     screen toggle doesn't return you to your original size.)
     Minor but irritating.

>   goes on?

a) Select the application, install the application, save the desktop.
b) It is saved on your system disk's resource file.
c) It means that GEM is informed about the run time requirements for
this particular program, i.e., is it a GEM application, or is it A "TOS"
application. If it is a TOS application, and you select TOS- takes parameters,
you can pass arguements to the program. If you save the desktop after
installing an application, all of this data is stored in a resource file.

Not that I know of. It would be nice though.

>   A discussion of the Games Computers Play graphics
>   bulletin board and what is available there.

Games Computers Play is not a graphics bulletin board. We are an online service with full screen graphics and multi-player games. We also offer email and easy communitions between people. Our graphics are not slow as most of them are stored on the users disk so that we don't have to download them. Also we use an error-dectection-retransmission protocol so that there are never any como errors in what you see. I had better stop or I will sound like a commerical, sorry if I allready do. Just wanted to let people know GCP is not just a BBS. Just one more thing GCP is currently ATARI only, i.e. we don't support any other machines.

Gregory F. Hogg
Games Computers Play, Inc.

P.S. I am just visiting the machine that I am posting this on and it is in no way involed in GCP. You can send mail to me here as I logon once or twice a week.

I just recieved my updated Hitchhiker's guide to bios from ATARI.

It came in a floppy with Micro Emacs (by Mark Williams Co.)
This is just a quickie, as I have not even printed out the tutorial for
micro_emacs yet, but am too excited about it to keep quiet.

Differences from MINCE.
=======================
1   Arrow keys work as you'd expect.
2   ^X2 creates a new window, but you re not limited to two.
3   ^X^B displays active buffers in a new window (like emacs
     and unlike mince).
4   has keyboard macros (^X(and ^X)).
5   The manual looks (I glanced at it with ``more'') complete.

I actually uploaded the manual, (>120000 bytes) so that I can get
a hard copy, but with kermit it took me an hour (9600baud connection).
It took only 90 minutes to upload a document of nearly the same size with a
1200 baud modem (so where's the bottleneck?).

There will be more later, unless someone else posts/mails a review before I
get around to it.

There is some good and bad news for Atari lovers in the latest issue
(Sept. 1985) of Computer Entertainer. The good news is that
Infocom is supporting the ST series of computers with their complete
line of text adventure games including their latest, A MIND FOREVER
VOYAGING (See my short review in net.games). The bad news is that
this games is designed for 128K machines only and will not be
released for the 8-bit machines (not even the 130XE apparently).
If this upsets you as much as it does me, write to Infocom and
let them know. Their address is:

          Infocom, Inc.
          55 Wheeler St.

Cambridge, MA 02138

Maybe, if enough people write, we can get them to change their mind.

I have a very quick question. Is the model 400 software compatable with
the model 800 software? Thanks.

Has anybody hooked a hard disk up to an ST? The HabaDisk isn't being sold yet. It seems to me that it shouldn't be too hard to use some other hard disk via some simple means like a special cable.

The "save desktop" option allows you to set your preferences the way you can on the LISA or Mac. On the Mac, most of your options such as double-click speed, volume etc. are stored in parameter-ram which is battery backed up, so it stays permanent (at least until the battery runs down). On the ST, preferences are stored on disk in a file called desktop.inf (on the disk that is in the drive *when the option is invoked*). In order to make your preferences "permanent", you should insert your system disk and save desktop so that from then on whenever the ST is booted, it will come up with those preferences. Among things like mouse click-rate and keyboard repeat speed, save desk-top will also save information regarding the installation of applications. For instance, if you install command.prg as a TOS application and then save desktop on your system disk, command.prg will run as a TOS application from ANY disk.

Hacking around with the ST, I have discovered a number of little interesting things listed below:

1. Reverse the ST screen to make it white on black and then use the vt52 desk accessory -- it looks great!

   To do this:
      1. select the control panel

2. pull the three controls for Red Green and Blue all the way
   down
3. quit the control panel
4. select vt52

This configuration also goes well with the command.tos program

2. Sitting in GEM, if you want to change disks without having to close the the current disks window and double clicking on the disk icon after changing disks, simply hit the ESC key while a disk-window is open. (This will not work if there is no disk-window open on the desktop)

Question time: Does anyone know how to transmit a BREAK signal using the vt52 DA?

Fact time: In last month's Byte (August 1985), on page 132-133, there were a number of machines benchmarked using a C program on page 133 (of the same issue). I ran the (EXACT) same program on ST after compiling with the development C compiler (DRI's C) and the results are tabulated below

n	XT	AT	11/750	11/780	DSI-32	
8191	11.6	3.7	2.41	1.90	1.85	
20000	35.3	8.13	6.11	3.04	4.52	
40000	351.5	99.71	13.13	6.38	9.04	

(All times in seconds)

For the ST
n = 8191 2.7? seconds
n = 20000 6.7 seconds
n = 40000 16 seconds

(All times may be +/- 0.2 seconds since I measured the times by hand)

For all kinds of details on the benchmark, refer to the magazine's article on the DSI-32 co-processor.

Please post questions etc. to the net

I am trying to fill out the control functions for the VT52 emulator on the Atari 520ST desktop. It is more than a straight VT52, since I have managed to figure out the following:

Sequence	Function	Sequence	Function
ESC A	Cursor up	ESC b_	Set char color
ESC B	Cursor down	ESC c_	Backgrnd color
ESC C	Cursor right	ESC d	Clear to BOS
ESC D	Cursor left	ESC e	Turn on cursor
ESC E	Clear screen	ESC f	Turn off cursor
ESC H	Home cursor	ESC k	Home cursor
ESC I	Insert line (here)	ESC l	Clear line
ESC J	Clear to EOS	ESC o	Clear to BOL
ESC K	Clear to EOL	ESC p	Inverse video
ESC L	Insert line above	ESC q	Normal video
ESC M	Delete line		
ESC Y__	VT52 Direct cursor addressing. Last 2 are address.		

where: BOL, EOL, BOS, EOS are beginning of line, end of line, beginning of screen and end of screen respectively. An underline is used to represent a variable argument character.

The ESC b and ESC c sequences are followed by a color selection byte where the last 2 or 4 bits (depending upon your screen mode) select the color. Default in 4 color mode is: 0 white, 1 red, 2 green and 3 black. I assume with black and white, you select with 1 bit. NOTE that you can hide characters by setting the color of the char and it's background the same.

Tabs work and seem to be hard wired every 8 columns.

I haven't been able to find character insert or delete functions.

This was discovered by trial and error in local mode (HALF duplex). Can anyone verify and/or add to this?

Rand Huntzinger

I had been thinking about a 256k expansion for the 800xl I bought in a firesale for $45.00, but somebody's beat me to it. Check the current issue of Byte (Sept.) for details. It uses 256k memory chips and a handful of glue chips for decode & refresh. Should be able to build it for about $50.00. Ramdisk software is provided on that stupid BBS system that Byte runs instead of printing code for articles. I find this an annoying policy that Byte adopted so that it has room for even more ads. This sure beats a 130XE: you've got room for 2 full single density ramdisks, or 1 DD ramdisk.

If anyone gets a copy of the software, please post.

As most people that get any type of magazine for the Atari know,
Computer Mail Order is running some super sales for the Atari.
They list several cartridges at $2.99 each with a minimum order of 10.
A couple of us ordered some of these cartridges. They come as bare
cartridges; no box, no instructions, no nothing. The end result is
that I am looking for some instructions. The two that we have that
we can't get anywhere on without instructions are:

Eastern Front
E.T.

The other cartridges I have are:

Pengo
Ms. PacMan
Dig Dug

If anyone has the instruction booklets for any of these games, especially
the first two, please send me email. I would be glad to pay postage and
copying fees if you have to use a pay type copying machine. Do not send
me anything without sending me email first. Thanks...

MICROWARE SYSTEMS CORPORATION
(515) 224-1929

Has already got a 68000 version of OS-9 with all sorts of neat toys included.
Are they doing a port?, When the released the radio shack (COCO) version,
the price was <$100 dollars (<$50?)?.

With amiga promising multi-tasking, It make sense that ATARIANS would want
the same thing. Besides, with OS-9's "dynamic library" (only what you need
in ram), it would give you more "usable memory".

Anybody from MICROWARE know anything about this.

If the theme of ATARI is "power without the price", I can't think of
anything more powerful than a "UN*X" system for under $1000.

Can anybody confirm the rumor that you can get a developer's kit free
if you have purchased the machine?

Both the Amiga and the ST have delayed putting their
operating systems in ROM. LET'S HOPE THEY NEVER DO!!!
Would you want to void your warranty to upgrade from
ms-dos 1.x to 2.x or 3.x? How about CP/M 1.x (there was such
a beast back in the days of toggle switches), 2.x 3.x,
or do you prefer Unix V6 to V7, 4.2, S3, S5?
Once an operating system is put in ROM, the machine that
contains the ROM, starts to become obsolete.

Besides, When there are no 'Guarenteed ROM Vectors' for
developers to go blythly jumping into, you eliminate future
'Compatibility Problems' (Try running 1-2-3 on a sanyo 550)
There is no "best way" to write software (bad ways and good ways yes!!).
one routine may be faster but requires more memory. That is
why lotus and flight-sim... go manipulating the hardware. The
could have sold the OS enhancement as a separate products, instead,
you have to put up with the slower ROM routines.

Maybe wth a little luck, we will see third party operating
systems that will provide transparency between the ST and AMIGA.
Micro-ware already has OS-9 for the 68000, maybe they'll port it
to these machines. (It may not be true UNIX, but it fits in anything).
How many people would buy a UNIX-like OS for $95.00 (the price for the
COCO version)?

Vendors of multi-user systems now have a 'workstation'
complete with graphics for the price of a Terminal. If either company
"burns-in" their OS, they will have shut the doors to hundreds of new
marketing possibilities.

Part of the popularity of the 'PC' (IBM style) is that, one disk can
run on more than one machine. There are few stores in my area that
carry a good selection of BOTH atari and commodore software, maybe
some third party effort could make selection easier.

Both machines appear to be well designed, AMIGA seems to be a little
too proprietary for my tastes, but in markets which IBM and APPLE seem
to have all but abandoned (high performance <$1500), this may be just
the "fire" we all need.

OS in ROM is great for cassette based machines (YEACH,GAG,ECK!!!) where
downloading the operating system from tape could take several hours. Both
ATARI and AMIGA were smart, they didn't try to get you to buy the system
with a cassete and "Upgrade to DISK" when your frustration level got
so high that you were ready to start from scratch.

Speaking of ROM upgrades, remember the COCO (TRS-80 Color Computer)?
There are bugs in 1.0 rom but the better ROMS are not available to
earlier COCO users. At $39, you can start all over again with the new

one. If you have "Extended basic", (makes the machine just usable),
double the above price. If you want your dealer to install them, he'll
charge for that. In fact, If you bring in a 16K machine that has been
upgraded to 64K, they will pull your chips out and put theirs in (for
an additional fee of course). The best trick of all is that you have to
upgrade the ROM to extended basic to get the Disk drive loaded so that
you can boot OS-9, which immediately throws away BASIC. Now that
Could have happened with these new machines.

They want to be able to have CD-ROM's, but as of yet, there is no "Universal
Standard" for such things. Suppose the Standard you buy is not the most
popular? I hope they dowload the drive controller.

How about networking? If anybody comes up with a "Universal Standard"
and your ROM can't handle it...

Either of these machines would make a nice workstation for a UN*X host,
but you can bet that if "POPPING THE ROM's' is required, that even
OEM's would rather "Pass it by" or "Start from scratch".

Suppose that next week, you were able to get a digital phone line (50KB)
an an X.25 modem. If your operating system didn't support that protocol,
Too bad, pop out another $100+.

Maybe someone will come up with a new media that will allow you to buy
one disk for ALL of the major machines.

Ram is like an automobile, you can go almost anywhere.
Rom is like a railroad, you go where it takes you.

Can anybody clarify the disk formats on these two machines?
AMIGA seems to be using 11 secs/track 512 bytes/sec
ATARI seems to be using 9 secs/track 512 bytes/sec
Are these figures right?

Any chance of getting them data-format compatible with each other?

*** READ THIS BEFORE FLAMING ***
This is posted for a friend of mine who has an ST and the developer's package;
I have neither and am doing this as a public (dis)service.

*** Begin Forwarded Message ***
I am sending a portion of the Hitchhikers Guide to the Bios. This
is a confidential document that Atari has sent to all of the developers.
However since most of the teminal escape functions have alread been
figured out this will clear up any problems. Also I see no reason
for this to be confidential.

These are the escape functions interpreted by the BIOS' conout() function. For the most part they emulate a VT-52 terminal [that's the easy one to do]. There are extensions to hack screen colors, control screen wrap, and a few other simple functions.

ESC A
Cursor Up
This sequence moves the cursor up one line. If the cursor is already on the top line of the screen, this sequence has no effect.

ESC B
Cursor Down
This moves the cursor down one line. If the cursor is already on the last line of the screen, this escape sequence has no effect.

ESC C
Cursor Forward
This moves the cursor one position to the right. If this function would move the cursor off the screen, this sequence has no effect.

ESC D
Cursor Backward
This move the cursor one position to the left. This is a non- destructive move because the character over which the cursor now rests is not replaced by a blank. If the cursor is already in column O, this escape sequence has no effect.

ESC E
Clear Screen (and Home Cursor)
This moves the cursor to column O, row I (the top

left-hand corner of the screen), and clears all characters from the screen.

ESC H
Home Cursor
This move the cursor to column 0, row 0. The screen is NOT cleared.

ESC I
Reverse Index
Moves the cursor to the same horizontal position on the preceding lines. If the cursor is on the top line, a scroll down is performed.

ESC J
Erase to End of Page
Erases all the information from cursor (including cursor position) to the end of the page.

ESC K
Clear to End of Line
This sequence clears the line from the current cursor position to the end of the line.

ESC L
Insert Line
Inserts a new blank line by moving the line that cursor is on, end all following lines, down one line. Then, the cursor is moved to the beginning of the new blank line.

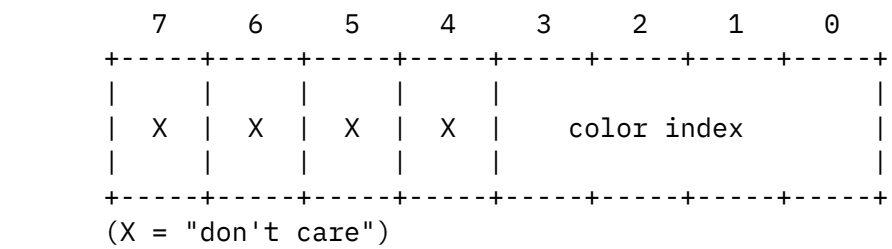
ESC M
Delete Line
Deletes the contents of the line that the cursor is on, places the cursor at the beginning of the line, moves all the following lines up one line, and adds a blank line at the bottom.

ESC Y
Position Cursor
The two characters that follow the "Y" specify the row and column to which the cursor is to be moved. The first character specifies the row, the second specifies the colum. Rows and columns number from 1 up.

ESC b
Set Foreground Color
The Foreground Color is the color in which the character is displayed.

Escape-b must be followed by a color selection character. Only the four least significant bits of the color character are used:

Bit Pattern of Control Byte:



(X = "don't care")

ESC c
Set Background Color

This function selects Background Color, the color of the cell that contains the characters.

Escape-c must be followed by a color selection character. Only the four least significant bits of the color character are used. (See diagram for ESC-b function)

ESC d
Erase Beginning of Display

This sequence erases from beginning of the display to the cursor position. The cursor position is erased also.

ESC e
Enable Cursor

This sequence causes the cursor to be invisible. The cursor may still be moved about on the display, using escape sequence defined in this appendix.

ESC f
Disable Cursor

This sequence causes the cursor to be invisible. The cursor may still be moved about on the display, using escape sequences defined in this appendix.

ESC j
Save Cursor Position

This sequence preserves the current cursor position. You can restore the cursor to the previously saved position with ESC-k.

ESC k
Restore Cursor Position

This sequence restores the cursor to a previously saved position. If you use this sequence without having previously saved the cursor position, then the cursor is moved to the home position, the top left-hand corner of the screen.

ESC l
Erase Entire Line
This sequence erases an entire line and moves the cursor to the leftmost column.

ESC o
Erase Beginning of Line
Erases from the beginning of the line to the cursor and includes the cursor position.

ESC p
Enter Reverse Video Mode
Enters the reverse video mode so that characters are displayed as background color characters on a foreground colored cell.

ESC q
Exit Reverse Video Mode
Exits the reverse video mode.

ESC v
Wrap at End of Line
This sequence causes the first character past the last displayable position on a line to be automatically placed in the first character position on the next line. The page scrolls up if necessary.

ESC w
Discard at End of Line
Following invocation of this sequence, after the last displayable character on a line has been reached, the characters overprint. Therefore, only the last character received is displayed in the last column position.

I realy recommend that anyone interested in working on the ST become a registered developer. The software developers package costs $300. It includes 8 diskettes: TOS, Logo, Resource editor, C compiler & assembler, linker, Mince, Micro Emacs, and a utilities disk. You also get over 2000 pages of documentation. There is also a number you can call and get information (It really works too).

TOS and Logo are same ones that come when you by the system.

The resource editor disk has a couple of sample resources. There seems to be several problems with the resource editor. The main one, is it displays things differently than a program does. Alerts in the editor do not look anything line they do in a progam. This is not really a problem since alerts are really a "black box". The major problem is with menus and dialogs. Both of them are squished vertically. You need to resize every object so that it looks right. This is something

of a pain since you have to leave the resource editor and execute your application to see if they look right.

The Compiler disk containes the 3 Pass Digital Research Compliler and their Assembler. The compiler puts out assembler code so it really takes 4 passed to complile a program. The documentation for the compiler is the standard CP/M-68K documentation. This can cause some really problems since the ST is not really running CP/M-68K but GEM-DOS. However the major problem is with the libraries. All of the routines in the libraries appear to be there, but they do not all seem to work. sprintf is there, but when you link it in you get several undefined symbols from the linker. The program still works though. I have not tried printf or fprintf. Open, close, read, write, malloc, and free are there but they do not seem to work at all. However Atari provided a include file "osbind.h" that provides macros called Fopen, Fclose, Fread, Malloc, and Mfree that do work but have a slightly different set of parameters. There are 10 .h files included on the complier disk. You almost have to read each one to figure out which ones you need to include. Another problem, if you only have a single disk drive system. You run out of room on your compiler disk if your file is larger than about 15K.

The linker disk has five separate libraries that you need to include for most application. Using the linker is a lot easier than using the compiler.

The utilities disk contains:

command.prg	the command line interpeter
dump.prg	a hex dumper
find.prg	similar the the MSDOS find
high.prg	puts the ST into medium res
low.prg	puts the ST into low res
kermit.prg	A poor but usable version of kermit
nm68.prg	A symbol table dumper
sid.prg	A debuger
size68.prg	A segment size utility

There is a way to make the ST come up into the command line mode on boot. You create a folder called "auto" on your boot disk. Then the ST will execute any program with a .prg extenction that is in that folder. (I have not tried this.)

Rumors:

The roms will not be available until December.

Hard disks from Atari will not be available until december.

A 512K internal expansion board for $300 will be available from a third party vendor in the next few months.

Atari is going to try and get royalties from Commodor for each Amiga that they sell.

Requests:

     Has anyone written a program that will allow transfer of binary
     files for the ST over the net?

I don't have an ST, but you may find the following amusing:

 DTACK GROUNDED, The Journal of Simple 68000/32081 Systems
 Issue #45 (and last) September 1985 Not Copyrighted

 :::(From Page 4):::
"The very brief operating manual explains that 'click' means to press the
 left button on the mouse and to quickly release the button. That seems
 to work fine, as well as the use of the ball on the bottom of the mouse
 to drag the arrow around on the screen. But then the introduction tells
 us to 'double click', without defining the term. By experiment, we learned
 that 'double click' apparently meant to click both the left and right button
 simultaneously. However, we could only get this to work right one time in
 three attempts. We decided we were clutzy and let James S., who was watching

the proceedings with amusement, give it a try. Same result. So we invoked the Control Panel and changed the response time setting of the mouse. No difference. Something is either wrong with us or the 'double click' software. (Yes, we tried placing one finger over both buttons to improve the simultaniety of the 'double click'. Didn't help.) By the way, after about 2.5 hours, the middle finger of our right hand, the one we would like to use to display the Italian fertility symbol to the mouse's inventor, got cramps from repeated unsuccessful 'double clicks'.
[The next day: by changing the response time of the mouse we can improve our average success rate on double clicks to about 70% - still annoying.]"

:::(From Page 28, Left Column):::
"THIS NEWSLETTER HAS BEEN PUBLISHED BY:

DIGITAL ACOUSTICS
1415 E. McFadden, Ste. F
SANTA ANA CA 92705 "

:::(From Page 28, Right Column, End):::
"SUBSCRIPTION FULLFILLMENT:

Most of your subscriptions expire with issue #48. Since we don't want Death March Dunkerson to get terminal hard-cramp writing $4.50 checks, we are negotiating with another newsletter writer to fill out your subscription. Since this guy is a better writer than we are, you will come out ahead on the deal. Different arrangements will be made for the several subscribers with a LONG time to go on their subscriptions.

If YOU decide to write a newsletter, remember that the real trick is to stop writing EXACTLY at the end of the"
[sic]

My comment: Well, I figured this would happen. Ole' FNE is going to be a real hard act to follow. I would advise strongly against flaming Digital Acoustics or the FNE over this, as anyone who was a subscriber got their money's worth once they had their hands on even one issue. The real pity is that we'll probably never see a FNE style cross-evaluation, normalized as to features/dollars, between the ST and the yet non-existent Amiga. I wish the new editors success in their effort, and I sincerely hope they keep the same spirit that was the brilliant life-force of DTACK Grounded.

By popular demand, this is a reposting of my comparison between
the Atari 520ST and the Amiga, as well as Eric L's added comments.

 Here are some corrections to Jan Gray's Amiga/ST comparison. My
corrections look like TECO comments (!* xxx !)...

	Atari 520ST	Commodore Amiga
processor	8 MHz 68000	8 Mhz 68000 !* 7.8Mhz !
RAM	512K	256K + 256K expansion board !* 8 Meg externally !
ROM	little (later, 192K?) GEM may be available in ROMs	192K

	sometime around August, for a $40 upgrade fee.	
expansion connectors	128K ROM cartridge slot, hard disk (DMA), floppy disk, modem (RS-232), printer (Centronics), monochrome/colour monitor, MIDI in and out, joystick and mouse ports. !* Connector for RF Mod !	256K RAM slot, full system bus connector(!), floppy disk,modem (RS-232), printer (Centronics), stereo RCA audio plugs, RGB monitor, TV/MOD? and NTSC video, joystick and mouse ports.
graphics resolution	640 X 400 monochrome 640 X 200 4 colours 320 X 200 16 colours 320 X 200 32 colours (plus some ability to display different resolutions on different parts of screen) !* Special 'hold and modify mode allows displaying all 4096 colors at once. Sprites and 'blobs' (blitter objects)!	640 X 400 16 colours 640 X 200 16 colours 320 X 400 32 colours
palette size	512 colours	4096 colours
fancy graphics hardware	no? !* Yes, and sprites !	bitblt in VLSI?
video outputs	monochrome, RGB	analog RGB, digital RGB, NTSC
sound hardware	GI sound chip (AY-8910?) Three voices, 30-20000 Hz, programmable waveform, envelope, and filters. !* Custom VLSI, stero output. Four channels (multiple voices on each). Plus digital sampling capability. !	Who knows? Stereo sound generation, and some special functions in VLSI?
keyboard	part of unit; function keys, numeric keypad, cursor keys, HELP and UNDO keys(!)	detachable; function keys, numeric keypad, cursor keys !* Slides under main unit !
floppies	3.5" floppy, holds 350K (formatted), attached by expansion connector, more floppies daisy chained? !* May daisy chain up to 3 external floppies !	3.5" floppy, holds 880K (formatted?), built-in. Expansion connector for second drive.
hard disk	15 Mbytes, $500? Attaches to DMA and hard disk expansion connector (built-in).	20 Mbytes (from Tecmar), $1000? Attaches to system expansion bus.

IBM compat. no yes, via $500 Trump card
!* Check that - IBM stuff
is done in sofware. If you
want a 5-1/4" drive, add
~$300 !

OS GEM and TOS (CPM/68K) Intuition and AmigaDOS
Similar to Mac Finder Similar to Mac Finder?
(multitasking!)
!* Similiar only in that
they both use windows and
icons. Amiga option lets
you use CLI, a Command Line
Interface smiliar to MS-DOS.!

future peripherals compact disk ROM (holds MBytes of data); 800K floppy; cheap graphics printers 500 Trump card ($500); digitizer; "Genlock Interface" (merges video with screen images); frame grabber; MIDI interface; music keyboard; multifunction accessory card (2 Mbytes of RAM, serial port, printer port or Winchester interface, and power supply); Pitchwriter ("sound grabber"?)

mass market versions Atari 260STD Doubtful.
!* Maybe later next year, but
Commodore will maintain a
minimum 30% profit margin
for dealers !

general availability Real soon now. Real soon now?
!* Sept. 15 !

software Real soon now. Real soon now.
!* Some packages available
even now. At least 20 will
be available on Sept 15 !

price $800 (Atari 520ST with high res. monochrome monitor, mouse, and 350K floppy drive) $2000 (Commodore Amiga with 256K of memory, built in 880K floppy, and mouse ($1300), plus 256K board ($200), plus high resolution colour monitor ($500).

>The Amiga, with all of its special function VLSIs, seems to be the
>better machine -- but is it worth 2.5X as much as the Atari 520ST?
>How badly do *you* want multitasking and spiffing graphics?

The Amiga is faster, more expandable has more built in and is

generally more powerfull by a large margin.

Eric

Subject: BYTE and ATARI ?!?

What about Byte magazine and Atari 520ST?? Why is the brand
new hacker machine never a subject of any Byte issue?? A
technical magazine like Byte should report about such
computers. They did it both with the Mac and the Amiga,
but why not with the new Atari. Are there any political
reasons?? I'm intersted in any information!

I have been following this discussion with interest and have one question- WHO have you guys called to get your kits? The Atari reps I have talked to have said things like "Oh, yeah- they made those for a while and sold them for around $2000" (!!!). Please write me with a person's name and telephone number if you have actually succeeded in getting a Developer's kit for $300. THANKS!

I had enough requests to justify sending this out to all of you at info-st.
Good luck with the modification. Cheers will be appreciated, as well as

examples of use of the full 1 Meg - it's lonely at the top.

Directions for expanding the Atari 520ST memory to 1 MByte

WARNING : This is a hardware modification that will void the warranty of your 520ST. If you do not have the appropriate tools or experience you have a substantial chance of ruining your 520ST. Proceed at your own risk ! This modification has been in my 520ST without any problems for 6 days now. However, I have (of course) not checked with knowledgable sources at Atari to verify if this modification endangers the long term machine reliability and/or software compatibility (I suspect it may endanger their software compatibility if enough of us do it !).

tools/components needed :

16 256k * 1 RAM chips, 150 nSec. access time type, e.g. NEC 41256C-15. (available at e.g. Fry's Electronics, Sunnyvale, CA for $ 2.77 each)

A good quality, preferrably temperature controlled soldering iron, with a miniature tip (tip should be narrow enough to avoid touching 2 I.C. pins at the same time). E.g. Weller type soldering station.

Good quality resin core solder (thin).

Approximately 4 foot of wire-wrap wire and a good stripper for it. (you will have to route 3 wire's over a sequence of I.C. pins. The easiest way to do this is to have a stripper allowing you to shift the isolation forward over the wire, solder the next point, measure new length, shift over insulation etc. until the endpoint). The "No Nik" .014" (dark green handle) wire wrap stripper is the best tool for this. Available e.g. at Jensen tools, Phoenix, AZ (602) 968-6231 catalog no H4B305.

De-soldering wick and solder suction tool.

Philips type screwdriver (for opening your ST), tweezers, pliers etc.

A steady hand and self-confidence.

explanation of the modification :

(Please read the rest of this document before starting. It may save you time and a 520ST)

The current memory inside the 520ST consists of 16 256k*1 RAM chips.
Address (A0..A8) lines are common to all those chips.
The WriteEnable line is also common to all chips.
Data (in and out) lines are (of course) individual. The RAS (Row-Address Strobe) line is common to all chips. The 8 chips forming the high order byte group have one common CAS line, and the 8 forming the low order byte group

have one common CAS line (CAS is used as enable for write operations,
suchthat WriteEnable can be common to both groups).
The high order group from MSB to LSB consists of U45,44,43,42,38,34,33,32.
The low order group of U30,29,28,25,24,18,17,16. Note that all chips are
adjacent, though the numbering has gaps. RAS0, CAS0H and CAS0L are supplied
from U15 pin 8,6 and 7 respectively. (The 0 indicates bank 0)

Bank 1 that you are going to build in will be "piggy-backed" on
top of the current chips, where all pins of the new chips EXCEPT RAS (pin 4)
and CAS (pin 15) are soldered to the old chips equivalent pin. Thus they will
end up sharing addresses, data, WriteEnable and power and ground with the
existing chips.

All RAS pins of the new chips are wired together and will be supplied with
the "RAS1" signal generated on pin 18 of U15 (the Memory Controller, marked
3H-2119CC or so).
The CAS pins of the 8 new high order byte chips (on top of U45..U32)
are wired together and supplied from the "CAS1H" signal generated on
pin 22 of U15.
Analogously, the CAS pins of the new U30 to U16 are wired together and
supplied with "CAS1L" from pin 21 of U15.

how to go about it :
====================

step 1 : Open up your 520ST, pull of the keyboard connector, and remove
         the main circuit card from its top and bottom shielding.
         Make sure to remember which screws go where and note the
         keyboard connector orientation.

step 2 : Desolder all the capacitors adjacent to the existing RAM chips.
         (DO NOT SKIP THIS STEP. You'll loose time if you do, and worse,
         the modification will not be reliable since you can't solder
         the pins obstructed by the capacitors reliably (if at all)).
         To desolder them, I found it easiest to heat the island on the
         non component side, and bend the wires straight. After doing that
         for each capacitor, turn over to the component side and heat the
         islands while pulling the capacitor out with tweezers.

step 3 : Open up the holes of all the desoldered capacitors, using a
         combination of de-soldering wick and suction tool. Do this from
         the non-component side. If certain holes are difficult to open
         up, you may want to use a wood splinter. (push it through while
         heating). Be carefull to remove all solder debris !
         THE REASON for opening the holes NOW is that they will be less
         accessible once you've done the other steps ! Patience is a virtue.

(NOTE : Step 2 and 3 are the only ones that may damage your ST PCboard.
Be sure not to use excessive force while pulling out the capacitors. If
you damage your PCboard anyway, cure the problem now and not later).

step 4 : In this step we will piggyback the new RAM's on top of the old ones.
         Be sure to connect all pins except pin 4 (RAS) and 15 (CAS).

The best way to go about this is to do chip by chip. First bend the pins of the new RAM's suchthat they are perpendicular to the package (instead of having slightly spread "cowboy legs"). Use pliers to bend pin 4 and 15 suchthat it comes out of the I.C. package horizontal, and cut of the excess length of pins 4 and 15 (I mean part of the pin, you still need to be able to solder to it!). Make sure that the new RAM fits snugly on top of the old one (in the same orientation !!!!), without intervening space and with the new pins touching the old ones. Now solder
each pin (except the non-touching 4 and 15) to the other RAM's. The best way to do this with least chance of damage is to touch both the new RAM's pin and the old RAM's pin. Heat them both for a second and add A LITTLE solder then. Wait till the solder flows. After each IC, check all pins carefully to assure a good connection. (use a magnifying glass)
NOTE : This step is crucial for the long term reliability of the memory extension. A badly soldered joint may show up later as sporadic memory errors. TAKE YOUR TIME.

(NOTE : until step 6 is finished, do not in any way apply power to your ST. This intermediate state of affairs will damage your memory chips !)

step 5 : Re- mount all the desoldered capacitors. Bend the pins like they were before re-soldering, suchthat they will not touch the lower shielding. Solder from the non-component side.

step 6 : In this step you will route the 3 wires mentioned earlier. The first wire connects pin 4 (RAS) of all new RAM's to pin 18 of U15. The second wire connects pin 15(CAS) of the new U45 to U32 to pin 22 (CAS1H) of U15. The third wire connects pin 15 (CAS) of the new U30 to U16 to pin 21 of U15.
The best way to do this is to use the stripper to remove 5 inches of isolation. Solder the first IC pin to the end of the blank wire, measure the distance to the next pin in sequence and shift over that amount of isolation. Continue in this fashion untill all pins in the sequence are done.
Work from U45 to the left, soldering directly to the leftover pins on the new chips. Make sure that no wire or solder sticks out above the top plane of the new chips, since they will almost touch the top shielding !
Route the wires through the PC board hole below and to the left of U15 to connect to U15 on the non-component side.

step 7 : Sit back. Use brain. Do you feel confident about the quality of your work ? No mistakes ? Check everything once again if you are but a little uncertain. Applying power with errors might make your ST into a decorative, non-functional piece of art.
OK. Either rebuild your ST into its shielding and cabinet, or put it onto a surface clear of wires and solder-remains and connect it to monitor, disk and supply. Boot it.

If it boots, you're probably there. Test if the new memory works by looking at the phystop variable ($42E) with SID if you have the

developper stuff. It should read $100000 (1M hex). Also note that
memcntlr ($424) now holds 5 instead of 4, and that v_bas_ad ($44E)
now holds $F80000 (screen bitmap origin).
If you don't have the developper stuff, try a single drive copy and
check that you get the whole disk in one buffer instead of two.

If the new memory does not seem to exist, use SID to deposit and
retrieve words on locations $80000 and up (1/2 M hex). If bit errors
occur, the ST bootROM did not detect the extension (it checks all
bits of 512 locations by testing a pseudo random sequence, before
accepting a memory bank). Try to pinpoint the faulty chip(s) and
remove the error.

If it doesn't boot, you're in trouble. I'm sorry. It is difficult
to give hints on what to do here. So many possibilities.
Desoldering the new chips probably won't work (if the old ones
were functional, the ST would still boot). Check for hidden
short-circuit on RAM pins. May also be that you have a flaky
new pin connection.
Good luck. I feel bad. Well, I might be able to help you a little,
call me when you're really stuck ! Evenings at (415) 965-7696.
Not after september - I'll be out of USA by then.

PLEASE :
========

Let me know if you did the modification and failed or succeeded. I'd like
to know how many people benefit from this and if it's safe enough for large
scale application. Mail to arpanet address gert@su-pescadero.

 HOW I MADE AN IBM-ST
 (ST WITH 5 1/4" DISK ACCESS)

   By DAVID SMALL

You can read and write IBM PC disks
on your Atari ST -- if you connect a
40-track 5 1/4-inch disk drive to your 3
1/2-inch disk drive.

Or...if you don't need IBM file
compatibility for an ST, you can connect
a 2-sided, 80-track, 5 1/4-inch drive
and store 720K on one disk. This will
save you money because 5 1/4-inch disks
and drives are cheaper than 3 1/2-inch
disks and drives.

But can you use the disk drive from
your 8-bit Atari? Not if the drive is an
810, 1050, or an Atari workalike such as
an Indus, Astra, or Rana. However,
ATR8000 and Percom drives will work.

They are "industry standard" drives that communicate via standard 34-pin interlace connector.

THE WARNING

Before actually telling how to hook up a 5 1/4-inch drive to your ST, we must caution you this is no job for electronics beginners. You need to solder and to understand the circuitry of whatever 5 1/4-inch you are using. Debugging your new system can be a frustrating experience. Not only that, open up your ST drive and you'll violate the warranty.

RIBBONS AND PINS

Of the 34 pins in the standard industry connector, only about 14 are used. The Atari ST brings these 14 wires out in a short, thick cable that plugs from the ST into the first drive's IN connector. This cable uses a non-standard 14-pin DIN connector, but it carries industry standard signals. Our goal is to get those signals to a standard 34-pin connctor and thus to a standard disk drive.

Theoretically we'd put a 34-pin edge connector on one end of a ribbon cable, 14-pin DIN connector on the other, and we'd have our disk drive cable. However, in practice I couldn't find a 14-pin DIN connector.

INSIDE THE DRIVE

Therefore, the method I chose to use was to tap into the signals inside the 3 1/2-inch ST drive. Besides voiding your warranty, this will probably require you to cut a slot in the drive case for the new ribbon cable.

If you open up the drive (use a phillips screwdriver) you'll find the

14-pin DIN connector expands to (Surprise!) an industry standard 34-pin ribbon cable.

Of course, it does this inside the shield to prevent radio noise from leaking out. A small circuit board has the two 14-pin connectors (IN and OUT) mounted on it, and it connects to the 34-pin ribbon cable inside the drive.

I put a "tap" from the 34-pin ribbon cable in the drive to the 34-pin ribbon cable running to my remote 5 1/4-inch disk drive. I then used a DB-40, 40-pin male and female clamp-on connector to clamp one side to the ribbon cable and the other to the remote drive's cable. Then I plugged the two DB-40s together.

You don't have to use a DB-40. Any clamp-on connector that covers the first 34 pins will work fine.

KINKY WIRING

But there's a catch. Atari does something kinky with the drive B select signal. It's on pin 6 of the DIN connector when coming from the ST. But inside drive A it is switched from IN connector pin 6, to OUT connector pin 5, where it becomes drive select for drive B.

This means Atari ST drives always listen on pin 5 for select, and the daisy chain scheme gives the proper drive the correct signal. Thus the two connectors on the back of the ST drive are not interchangeable, like other Atari drives. Plug your ST into the OUT connector, the drive won't work, period.

Therefore we have to jump from pin 6 of the DIN connect (drive B select) to pin 12 of the ribbon cable (drive B select) to get this signal across. Otherwise it doesn't show up on the 34-pin cable otherwise. This is easy to do on the bottom of the 3 1/2-inch drive's DIN connect board.

Now we need to set the remote drive as drive B. Sometimes it's called drive 1 or drive 2, depending on whether the manufacturer numbers drives at 0 or 1.

When a drive is idle, a five-volt signal (HIGH) exists on the BUSY line. When the computer wants to access the drive, it pulls down this signal to zero (LOW).When the computer is finished with the drive, it releases the signal and the drive "pulls up" the signal to its original five volts. If two drives are hooked up, only one may contain pull up circuitry because the computer can only pull down five volts.

Pull-up circuitry usually is contained in a chip in the drive. And now you are at a point where you must know enough about your 5 1/4-inch drive to figure out where the chip is.

Since the ST drive A contains all the pull-up termination circuitry we need we must remove termination packs from the remote drive. In the case of my Tandon TM-100-2 drive I also needed to deal with the select line termination, since it doesn't go through the resistor pack. I had to clip resistor R14 from my Tandon to get rid of the added termination.

Special Note: The ST monitor throws out a lots of magnetism. If you don't keep your drive at least one foot from the monitor, the disk's heads will pick up the monitor's signals and confuse he read data. You'll immediately notice data error if you get your drive close to the monitor. This is good reason to use a fairly long ribbon cable (3 feet or so) (We haven't noticed this problem in-house. ANTIC ED)

ALL DONE

All right, assume you have added an 80-track drive. Put the disk in, close the door and turn on the system. Click

on drive B, select FORMAT, and format
the disk either single-sided or
double-sided.

>From then on, treat the 80-track
drive as an Atari ST drive. Note: 80
track drives have traditionally been
persnickety, which is why 40-track
drives remain popular. Keep a sharp eye
on the drive's alignment. It takes very
little misalignment to make a disk that
only one 80-track drive in the whole
world can read.

If you've added a 40-track drive, you
may use it as an ST drive in only a
limited fashion. You can't use FORMAT
or a track copy, because they'll try to
force the drive past its 40th track.

   IBM ST

On the other hand, you can put an IBM
PC disk in that 40-track drive, and
click on the B icon. It'll pull up the
disk's directory into folders and "text
only" files.

You'll notice on the top of the
window an PC-DOS type of "pathname"
consisting of multiple (if needed)
folders and a file name. GEM simply
turns the concept of pathnames into
folder icons and moves you through the
path by your actions of selecting,
opening, or closing a folder.

Of course, you can't run IBM programs
because they are written in IBM assembly
language, which the ST cannot
understand. However, you can freely
copy and use text files and the data
within them. Furthermore, if you write
back out from the ST to the PC disk,
you'll find that an IBM has no trouble
reading what you wrote.

I do not know whether it is true of the U.S. version (I suspect it is)
but the U.K. VT52 emulator does not bind the cursor keys (or the function
keys). In addition the single quote character is bound to colon.
DESK1.ACC contains no calls to "trap 14,16" so must use the key bindings in
the BIOS. The single quote thing is probably a coding error.
Has anybody written a terminal emulator yet that does not have these problems?
If so *please* e-mail me a copy.

Thanks

>Both the Amiga and the ST have delayed putting their
>operating systems in ROM. LET'S HOPE THEY NEVER DO!!!

I agree with the spirit of your posting. Unfortunately on the Atari,
with the DOS in RAM, not much memory is left for applications.

Obviously the thing to do is increase the RAM.

In the very near future (like really soon) I'm going to be starting
on several papers required for courses toward an MS degree. What I
need from NETLAND are recommendations as to what word processing
package is best for my needs. I currently have the ATARI WRITER and
the ATARI WORD PROCESSOR but feel there must be something better.
I've read the ads (articles) in the mags but have been left with the
impression that they were leaving alot out. I currently have a 1200XL
(maybe soon to be a 130XL), a RANA disk drive, and a GEMINI 10X
printer. Intend to add a computer interfacable typewriter soon.
Any comments (good or bad) about the various items of word processing
software or computer interfacable typewriters is most welcome.
If there is overwelming response I'll gladly post results to net.
Thanks. ejc.

I would also be very interested in why Byte has managed to ignore
such a provacative combination of price and utility. I suspect that
Jack Tramiel opted not to play up to them and they responded by
blacklisting it. It does not speak very well for Byte's interest in
their readers. I for one lost a lot of respect for Byte because of
this glaring omission.

The confusion here is that the Atari reps were talking about a
Hardware *and* Software package available a long time ago. The
$300 package is *just* software and is available only after you
have proof of purchase of an atari ST.

Has anyone with an Atari ST development system located a decent (hopefully

inexpensive) editor yet? The documentation mentioned Mince - are there
any others to choose from? How have people been developing software for
this machine without the use of an editor (or is there an in-house version)?

Thanks in advance,
Ed Friedman

I have heard (from someone looking under the hood) that the Atari 520ST
has a chip labelled "MMU". Is this an MMU? Is it any good? If so, this
would seem to be a significant advantage for the ST.

Ease up on Byte magazine.

You should note that Byte has several kinds of features on machines.
One kind is a preview, which is not really a review. These are done
months before the machine makes it to market and depends on the
manufacturer letting Byte come in and playing with one of their
pre-production models. The Mac was previewed by Byte (in October?) in
this way. Besides the previews there are also the official reviews
which take place on released hardware. Because these have to take
place after the machine has come out you will probably see it several
months later (because of publication lag, etc.)

I suspect that either Byte couldn't get to see a pre-production Atari,
or it was not clear that the pre-production model was close enough to
production quality. When they previewed the Amiga Byte said that the
ROMs were still being worked on, but they seemed sufficiently close to
the final product to preview. Expect a review 3-4 months after the
machine has come out (assuming also that Atari gives Byte a machine to
review.)

There is an ad in the October Issue of Analog Computing for a company
called Gizzmoz that are selling things for the ST already. In their
ad they list one of the packages available as: "ST" Development Software
Package. They don't give a price. You have to call. Their number
(in Mass.) is (617)-371-1855. If anyone calls and gets their price,
post it in this newsgroup.

I am interested in interfacing some magic hardware to an ST.
I see two possibilities: the DMA port and the cartridge slot.
However, this hardware needs to be written to and
>>>>>>>>>> the cartridge slot does not have R/W! <<<<<<<<<<
I couldn't believe this when I saw it but it's true. However,
this can be probably be overcome by using a high-order address
line as R/W and agreeing to write only to one half of the
address space and to read only from the other half. See any
problems with this? Excepting "Yeccchhh!", of course.
The problem with the DMA port is that I don't know how it works.
Can anyone enlighten me? DMA would be nice for this particular
hardware.

I hope I get flamed on this, I hope I am wrong, and I hope that
something can be done soon, but,

After looking at the cartridge pinout on the 520-ST in the back of the Owners manual, I realised that any hope of ram expansion without tearing into the box itself were dashed. D0-D16, A1-A15, UDS, LDS, +5, Gnd and two ROM-SELECTS were all that appeared to be drawn out. Two pins were used for ground and two for +5.

I suppose for $800, I shouldn't really expect a 7 slot backplane, but they should have brought out at least 7 of the other address pins, and R/W pins, a 50 pin rather than a 40 pin card would have enabled expansion for anything but Co-processors (bus is already kind of busy). I guess everybody has to screw up something.

Even the "Doorstop Sinclair" was more 'open' than the 'ST'. One of the "Expansion options" for the ZX-80 was real cute, A ribbon cable with 6 "slots" on it. Expansion cartridges were just "Stacked Up" and plugged into the ribbon (RFI was a bit sticky, but aluminum paint helped that).

On the flip side, the "Hard disk port" looks an awfull lot like a 488 bus to me. Anybody tried interfacing any 488/HPIB peripherals to it? If all that is needed is a RAM disk, the RAM drive could be stuffed on the hard port.

Went to an Atari users group meeting, only one of the 16 owners was even remotely less than satisfied. He was the only one without a developers kit and was "getting tired of running demo's". Seems that the developers kit would make a great RETAIL product.
(does anybody from ATARI read this net?)

One publisher appears to be delaying the release of their software until the OS is put in ROM. Appearently, they want to go jumping into the BIOS/BDOS the way Lotus did. Can't anybody write a KOSHER program?

Do Un*x programmers write APPLICATIONS that HACK UP the KERNAL?
(not OS drivers, but the applications which don't use the standard interface, ie: jump into the kernal)

How come the ST takes less time to load it's OS into RAM than it takes a MAC to boot up from ROM?

Someone read an article in the users group (newspaper) that said AT&T was going to OEM ST's. Will they run UNIX? How about a GEM/UNIX combination?

Anybody heard of any Smalltalk-like devopement for the ST?

(These opinions used to be mine but I'm giving them up for adoption)

I just played with some ST's at the King of Prussia shopping mall
(the country's largest!). I was extremely impressed with the ST. The
monochrome display was EXTREMELY sharp: it was just as sharp as the
MacIntosh, but with a larger display. I saw a demo of a super
spreadsheet program, which not only had multiple windows, but the
ability to adjust the font size in each: you could make the characters
and lines large enough to read across the room. Programs load and
execute VERY fast. Maybe the Amiga will do color better, but for black
and white, I suspect that all those chips are just wasted horsepower.
The dealers were particularly unhelpful, even for computer salespeople
(I suspect that there is an IQ test for becoming a computer
salesperson: if you score in 2 digits, you sell Apple and IBM; if you
score in 1 digit, you sell Atari; 3 digits and they throw you out). At
one place they had removed the mouse, and REFUSED to plug it in!
(Finally I discovered how to manipulate the curser and "click" from the
keyboard.) None the less, the machines were selling themselves.

One of the major factors that sold and continues to sell the Mac is its
sharp display. All the spinning cubes in the world won't help a user
if he can't read the text on the screen (and anyway, the ST can spin
cubes and bounce balls, even if it does so slower than the
Amiga.) Commadore really screwed up by not giving the Amiga a hi-res
non-interlaced display. A 200 line display is GARBAGE. Period.

I am amazed at how the ST is being ignored by the computer press.
Nothing touches it for price/performance. The Atari ads people are
complaining about are a lot more factual then 99% of the ads you see
(yeah, tell me why NRC "builds a better computer", why ATT "has the
future built in", or why "an Apple can balance your budget"; if you
want to flame, then flame about the AT ads which stress its enormous
address space, but don't mention that DOS can't use it...)

The editor-in-chief of BYTE (I think his last name is Lemman, or something like that) recently visited Atari. He then posted a lengthy article on Compuserve praising the ST and new developments going on at Atari. This all happened about three weeks ago. Your average magazine is about 3 months behind so it will take a while for articles to appear in BYTE reflecting this attitude. The "product preview" of the Amiga was not a review, but a description of the hardware. It was probably written by Commadore themselves.

> Has anyone with an Atari ST development system located a decent (hopefully
> inexpensive) editor yet?

If you bought the software developers package you should be getting MicroEmacs.
Otherwise there is another emacs clone, Mince, which is available.

MicroEmacs (ME) and Mince are very similar, with the following exceptions:

1) Mince can operate on very large files, using a temporary swap file
and a virtual memory mapping scheme. ME is like most micro text editors,
it can only operate on files that fit in RAM.

2) ME can open up more than 2 windows, MINCE is limited to 2.

3) ME has a macro feature, MINCE doesn't.

4) ME will fit on your C compiler disk, MINCE doesn't (at least not with the
standard 64K swap file.) This makes a difference if you, like me, are currently
stuck with 1 single sided drive.

5) ME is supposed to retail for around $50, MINCE sells for about $120.

Conclusion: either one is reasonable for text editing. Neither one is a
GEM application, nor do they exactly knock your socks off. Price is certainly
a factor. If you go for the software developers package, don't bother with
MINCE.

     I've noticed that some of you netters have an Atari 520ST
that comes with the built-in MIDI interface. I saw the ST
last night for the first time (I liked the graphics). I'd
appreciate it if you could post or send me some info on it's
capabilities. Also, if you know of any reviews/articles on the
MIDI capabilities of the ST, please point me in the right direction.

What MIDI software does the ST come with?

Is there any software for the ST (Atari or outside vendor) for archiving
synthesizer voices (particularly for the DX-7)?

Is there any synthesizer sequencing sofware for the ST?

Where can I get an ST and for how much? (I'm in the New York- Metro area).

TNX in advance,
Fritter WB2SPU

I really don't believe this is a fact.
Although the Amiga appears to use 64Kx4 on the main board, it does this
for the convenience of the video controller chip. Since the video controller
chip is supposedly limited to 512k bytes addressing range, there is no reason
memory hung on the side beyond the first 512k bytes need be 64kx4; 256kx1
will probably do quite nicely.

If you don't know the facts, R.T., don't claim you do. Thats why we have the word probably!

Summary: Responces to earlier questions.

-

A couple of weeks ago I posted an article asking how best to transmit
files and programs for machines like the Amiga and ST. These are the
responces that I received. Any more comments? I am going to ask in
net.micro.mac what they use and how well has it worked. I feel like
an infidel about to journey into the holy land :-). I will post any
interesting responces here.

Thanks to all who replied,
Tom Granvold

     Don't flame me for posting here; the issue is debatable.
     Compile and enjoy.

     This program has some simple ascii capture facilites that
     the DA does not have.

I have attached some messages from the Compuserve OS9 sig that may
be of interest.

dgc

**** Start of attached messages ****
#: 17200 S5/OS9 68000
    14-Sep-85 14:15:10
Sb: #17125-#Os9 on Atari 520st
Fm: Rich Smrcina 75036,163
To: Marc Limata/CT. MicroSys 72646,2666 (X)

Marc,
 How close is your company too deciding if you will do the port. And if
 you ddecide to do the port, what sort of time frame are we looking at.
 And (if your really ambitious) what cost?
     Rich

#: 17229 S5/OS9 68000
    15-Sep-85 10:24:25
Sb: #17200-#Os9 on Atari 520st
Fm: Marc Limata/CT. MicroSys 72646,2666
To: Rich Smrcina 75036,163 (X)

One of the factors in the decision is the finacial arrangement with Microware ,
if it is such that we have to charge $300 - $400 for the package (which is what
it is selling for on some machines) then we have to take a hard look at it
being a viable product. We think a $100-$150 price to the end user would be a
limit that most will pay , I am currently talking to dealers and distributors
to get an idea of volumes and pricing . We keep getting the same answers from
dealers ... why would anybody other than a present OS9 user pay $100 to $150
for a O.S when they get a free one with the machine?? That attitude from
dealers and a lack of interest at this point makes it rough for ANY company to
want to put money into that sort of project. WE are very interested and I
personally want OS9/68000 on the ST and as soon as a decision is made (possibly
in the next 2 weeks) we will announce the decision and projected release dates
of BETA copies
.... Thanx for your interest .... Marc

If/when you become relatively sure of it then alot more people will be
interested. Do you foresee a graphics interface? What qualifications would
one need to receive a beta-test copy?
           Rich

Attached is a message from the Compuserve Atari Sig that might
be of interest.

dgc

**** Start of attached message ****
#: 125570 S5/ST Software
    18-Sep-85 22:06:41
Sb: Free Software from Atari
Fm: Atari Explorer 70007,1135
To: ALL

Next week, Atari Corp. will ship copies of 3 give-away programs. Copies will
go to ST dealers and to those user groups who participated in the rollout
program, but we encourage everyone to get copies freom each other. These
include: DOODLE, NEO-CHROME, and ST WRITER. Doodle is similar if not identical
to the one on this SIG. NEO-CHROME is a color drawing program for low res
which includes many features -- but which Atari will continue to enhance until
it is eventually released as a product. ST WRITER is a word processor
identical in function to the 8-bit AtariWriter. It includes a utility for

uploading 8-bit AtariWriter files to the ST. I have been working with NEO and ST WRITER (nicknamed "starry-writer" here) and they are both quite powerful and should tide people over until commercial packages hit the streets. In fact, the only reason why ST WRITER is a freebie is because it makes no use of the TOS/GEM functions and we wanted commercial packages with our name on them to take more advantage of the ST system. Watch this space for late-breaking news!
--->Neil Harris

My father has recently acquired an Atari 600XL as a premium. It has 16K RAM and is apparently a discontinued model, and none of the usual Atari dealers or toy stores seem to want to have anything to do with it. The local Atari users group had a good set of software on disk, but were unable to supply info about mundane items like the memory upgrade to 64K, how much memory you need to run the disk, etc.
It seems that all the Atari people are 520ST-crazy, and have forgotten about the older machines that are still being distributed.

Apparently very few 600XLs were made, but there are a lot of 400s and 800s and 1200XLs and 130XEs around. I am unsure about the relation ship among these machines and the 600XL. Are they software/DOS compatible? What about game or program cartridges?

Any information about the 600XL would be appreciated, especially a pointer to a source (store, mail order, or club) for the memory upgrade and game/program cartridges.

Thanks in advance,

Michael C. Berch

   I noticed atari modems in the Sept. BYTE for $30.00 from Computer Mail Order, and was kind of wondering about them: collecting dust in a box somewhere is an Atari 600XL, and I'd really like to turn the sucker into a home terminal of sorts. WILL THIS DO THE TRICK???? (I know what CMO will tell me :-)
   I don't have a disk drive, or anything else worthy of note. There is nothing I need to kermit, all I want is dial up to check my mail. Perhaps in the future I might get ambitious and build something that will give me 80 columns so I can use EMACS, but that is on a way-way-way back burner.
   If anyone can tell me all the dirt on the modem, I'd be most appreciative. Let me know any way you feel fitting....
              Thanx in advance,

Our local atari user group in the washington D.C. area has accumulated
some public domain software for the ST and is distributing for a very
reasonable cost namely $4.25/disk + .50 for the envelope. The stuff
isn't fantastic but it will give you a feel for the capabilities of the
machine. The titles currently available are

1) High Res. Monochrome Pictures Demo
2) Color Slide Show #1
3) 4xForth Demo Disk
4) ST terminal programs(one has xmodem upload/download I believe)
5) Sundog demo disk (Color only)
6) Color slide show #2 (Contains some nice pictures of the mandelbrot set)
7) Graphics demo disk
8) Sample c programs
9) Sample logo programs
10) Midi music programs
11) Ramdisk & docs (Gert's ramdisk program as well as instructions to
    upgrade to 1 meg)
12) Doodle program w/source (freeware)

Order from Current Notes, 122 N. Johnson Road, Sterling, Va 22170
Mail order price is $4.25/disk plus $0.50 for an envelope. If you
send $15 more you can also get a subscription to current notes which
was praised by John Dvorak in infoworld as one of the best users club
magazines. The magazine is currently mostly 800 stuff but there is a
rapidly growing ST section.

Dear Mr. Fritter;

So far, there is only Public domain software which uses the MIDI port.
It plays back a few songs which are on a pre-stored file, and provides
a simple graphics display that shows what notes are being played. There
is no capability to modify the notes, or to change the tempo, or to
record your own stuff. I think this package (MIDIDEMO) came from ATARI.
You should be seeing some good stuff within a month or two. In fact, I'm
writing something myself that will be roughly equivalent to what is
available for the C-64 or Apple line of computers.

I don't know where you got FASI, but the hard disk port is supposed to
be SCSI, with a 1.33 mb maximum transfer rate (almost faster than the
68000 can "copy" from a RAM disk). The pins available are the same
type that the HABBA drive uses on the MAC (inside the machine). There
a few drives that support the SCSI interfaces already available. In
fact, the developer's hard drives are apearently modified MAC drives
(different cable). From the AMPRO "Little Board" ads, it also appears
to enable interfacing to networks, I/O expansion... SCSI interface boards
are also available for the IBM PC. (Could there actually be a standard
developing here?).

Now, if we could just get someone to explain SCSI to us, we would know what
the limits are. Could you tell us more about the 5385 chip? What lines
does the ST seem to be missing?

Fm: Gary Yost 76703,1077
To: ed bartholomey 72507,257

There is work being done on this type of software. A few publishers are doing parallel work, and I wouldn't expect a full-featured notation package to be available until first quarter, 1986 at the earliest. There should be many bare-bones MIDI programs available before then, though. Hybrid Arts is doing an ST version of their Miditrack II software. I'd like to ask you... Would you like to see some sort of super-duper souped up Advanced Musicsystem for the ST with control over MIDI and the sound chip? I'd like to get as much reaction to that idea as possible. Thanks.

- Gary

Foist of all.... Are you the Art I met at the MacExpo in Boston a few weeks ago???. If you are, we are the Nifty Group, formerly MacNifty. Now only Nifty, as we finally got around to the ST, and are very impressed. Beginning Sept 15 we are going to begin to re-engineer our products for the ST as well as the Mac. The first product will be the sound digitizer and Stereo.
As far as the Casio products go, our intention is to provide them to the Micro/MIDI world at the least possible cost, to get them out to the Micro user, and Dealer. Someone seems to be missing the boat somewhere. If you would like to give me a call, our # is 1-800-328-0184. We are in Minneapolis. I will be more than happy to discuss our plans for marketing ST products as well as Casio. CIS doesn't like me to quote prices on the boards.

Fm: Gary Yost 76703,1077
To: Stan Kalisher 72257,2722

That's two potential customers, eh? Duly noted, and I hope more people are interested. One thing I'd love to know is whether or not there would be a market for an Advanced Musicsystem-like product that took advantage of MIDI and/or the sound chip. Is there? What if it used all the available AMS files? About your digitizing project, could you please send me some email describing what you're doing exactly, as I know a lot of people who'd be interested in what you're doing. As we all know, the Amiga has fairly good analog/digital audio sampling techniques, and if the ST could do some of the same, even with add-one hardware through the DMA port, it would be interesting to see if you could get the hardware to install itself to look just like the Amiga speech vectors in AmigaDOS. Porting Amiga sound programs to the ST would then be a fairly simple process, and I hear that some of the products under development by Cherry Lane (?sp?) uses sampling plus AI routines that even lets the Amiga harmonize with you in real time while you're singing. Now, I don't know how many people want such a product, but I'm one of them. Audio and video digitizing is very exciting.

18-Sep-85 08:29:06
Sb: #125298-MIDI ST SOFTWARE
Fm: Gary Yost 76703,1077
To: CHARLES F. JOHNSON 75066,404

Charles, what do you like about the Hybrid Arts software, compared to Advanced Musicsystem-like notation software, and vica versa? A clear analysis of the benefits and drawbacks of the two types, from a musicians point of view, would help me a lot. Thanks.

- Gary

#: 125583 S5/ST Software
19-Sep-85 00:38:59
Sb: #125406-MIDI ST SOFTWARE
Fm: CHARLES F. JOHNSON 75066,404
To: Gary Yost 76703,1077

Gary... The thing I like the most about the Hybrid Arts software is the way it emulates a 16-track recording machine. It has auto-locate, punch-in and -out, and other features that make recording a part into the sequencer (computer) pretty easy. It also has a whole lot of MIDI mode commands and capabilities. You can change programs and record the changes as part of the data. The program also records pitch and mod wheel changes, so it really has a lot of features for the professional musician. The main drawback of the system as I see it is the complexity of the user interface. You have to know a multitude of key combinations in order to access the functions.

This might be an area where the ST's GEM environment could greatly aid the process of composing.

On the other hand, the notation style of composition has a lot to recommend it too. For one thing you don't have to actually be able to play the music (no matter how slow), and it's also possible to write things this way that might not occur to you otherwise. At this time there is no notation style MIDI system for Atari computers (that I know of anyway) so the Hybrid Arts software is kind of the only game in town right now.

What company do you work for? In addition to being a musician I also program in 6502 machine language (had a program published in ANALOG #35). I'm extremely interested in any applications using Atari and MIDI....

Hope this somewhat long-winded message is of some help to you...

#: 125724 S5/ST Software
19-Sep-85 22:17:43
Sb: #125583-MIDI ST SOFTWARE
Fm: Gary Yost 76703,1077
To: CHARLES F. JOHNSON 75066,404

Thank you very much for your feedback. Exactly the detail I wanted to get about the musician vs. notation style of MIDI software. Currently, I'm leaning towards the notation style, because there are more of us who can't play so well, but want to get the music in there and THEN start fooling around with the kind of sounds a CZ-101 can make. BTW, I work for Antic. Thanks again.

To: Michael Squire 75236,2640

Mike:
     We were worried about the same problem. Before we went ahead and designed
our 1 Meg ST upgrade board, we asked Atari if they were going to do anything
similar. They said no. (Well, at least for now...). And ours is designed so

that it COMES OUT EASILY. No soldering the main board, kludge, kludge... If Atari were foolish enough to insist that you had to buy THEIR board (which I harldy think is likely, considering how intelligent and responsive they've been so far) you could simply pull our board out, get whatever upgrade they were offering, and then plug our board back in. Simple, no? --alex

Mike:
An ST ram upgrade is very straight forward, unlike all this partitioned memory nonsense on some other machines, (including a machine that didn't have it in the processor chip, so they added it!). On the Atari, it's just contiguous memory. And a good add-on board (like ours, for example) should be able to plug in and plug out, so that should Atari suddenly turn demented and try and penalize users of 3rd party equipment, you can just pull the upgrade out. Try that with some of the Mac upgrades! --alex

Alex, I think it will be a little more complicated than merely plug and unplug the board! All the STs I have seen have the RAM chips _soldered_ into the board, not socketed. Have you checked on that? It doesn't stop me from being interested in buying it, but it _will_ make it more difficult to install for a lot of people.

    There's no theoretical difficulty about a 4 meg board. Your ST needs to have sockets for the RAM chips. The board is then designed to move the appropriate lines from the 1 meg chips to the same lines on 256K chips (the pinouts are not the same, and 1 meg chips have 2 more lines.) You need to run 1 additional wire from the controller to the board, making 4 lines total (instead of 3 for the 1 meg board). Shucks, we've got the board DESIGNED! But how much interest is there likely to be in it, when 1 meg chips are so bloody expensive? --alex

Jez:
    The memory controller, if you look close, has an extra address line coming out of it. It also has an (an?) another set of RAS and CAS lines for a second bank of memory. If you plug 256K chips in, you get 1Meg. If, however, you plug in 1Meg chips, and run that extra address line to them (I KNEW that thing was there for a reason!), you can get 4 meg, thusly: 2 banks of 16 1Meg chips-->better known as 4 sets of 8 1Meg chips, or (ta-da!) 4 meg. As for our board, if you don't want to desolder, (not surprisingly), you cut the chips that are there out (ok, so it's 40 bucks down the drain, big deal.). You then socket the spaces, and plug our board in, and run three jumpers to the memory controller. It's not a big deal for anyone who's halfway decent w/ a soldering iron (I did the preliminary one myself, and I'm four thumbed, if you know what I mean), because you're not soldering anything delicate, like memory parts. That's why we recommend just cutting the chips out... You CAN desolder 'em, but the extra effort required to do it right just isn't cost effective. And besides, what if you make 1 chip just >>slightly<< flaky?? Nightmare time... Just cut 'em out and be done with it... --alex

This is in response to an article by Rex Ballard which was a reply to a reply on Amiga memory management. Since the topic is the Atari ST I decided to post it here under a more suitable title. While I'm at it, I'll address a few points about the ST where there seems to be some confusion.

In article <270@ccivax.UUCP> rb@ccivax.UUCP (rex ballard) writes:
>
>"Presenting the ATARI ST" has a memory map on page 34 that show address
>$FF8000-$FF8200 labled "DATA CONFIGURATION", in the I/O region. If that
>ain't an MMU term, what is? (Interesting 512 bytes - 512K hmmm), if they
>send you a 68010 with your next OS, watch out!!!. Anybody look at those
>addresses?
>
>If this is the case, does that mean that the 512K in the machine is
>really the CACHE for an external RAM disk?
>

The schematics provided with the developer's kit does include a MMU chip, I haven't looked under the hood but by all reports it's there. Also, the machine was described as a 68010 based machine at one point in the documentation. This means they at least thought 68010 at one time, but doesn't indicate whether that might be a future upgrade.

You also mentioned TOS, which is reportedly a version of CP/M-68K. According to the documentation I have, it is not. TOS is a variant of a Digital Research operating system called GEMDOS, which looks very much like a 68K implementation of MS-DOS (or PC-DOS if you prefer). Like MS-DOS, it has a subset of commands which are CP/M compatible. The remaining entry points appear to be MS-DOS compatible. This must have been quite a help in porting GEM to the 68000. I expect we'll see GEMDOS appearing on other machines as well.

I don't have documentation on the PC-DOS bios, but I wouldn't be a bit suprised if the Atari BIOS resembles it in some form. In the HitchHikers Guide to the Bios, there are mention of things like "IBM-PC compatible keyscan codes". It appears that it should be comparatively easy to port programs between the Atari ST and the IBM-PC.

Despite comments to the contrary, the Atari ST operating system does not have GEM and the operating system squished together. According to the documentation you can boot the system without all of GEM and the desktop. I haven't tried this, but it is documented. A MS-DOS like command processor is available with the developers package which can run on top of the desktop or in its place.

Also, you do not have to include GEM commands in your applications to be able to run an application on the desktop. If your program doesn't use GEM, you can flag it as a TOS application and when it is started from the desktop the screen will clear and the program will run as if GEM wasn't there. If you write in C, you can use the standard I/O library to write to the screen.

Hopefully this will clear up some misconceptions about the ST and not introduce any misconceptions of my own.

Rand Huntzinger

Mike:
     We were worried about the same problem. Before we went ahead and designed our 1 Meg ST upgrade board, we asked Atari if they were going to do anything similar. They said no. (Well, at least for now...). And ours is designed so that it COMES OUT EASILY. No soldering the main board, kludge, kludge... If Atari were foolish enough to insist that you had to buy THEIR board (which I harldy think is likely, considering how intelligent and responsive they've been so far) you could simply pull our board out, get whatever upgrade they were offering, and then plug our board back in. Simple, no? --alex

    An ST ram upgrade is very straight forward, unlike all this partitioned memory nonsense on some other machines, (including a machine that didn't have it in the processor chip, so they added it!). On the Atari, it's just contiguous memory. And a good add-on board (like ours, for example) should be able to plug in and plug out, so that should Atari suddenly turn demented and try and penalize users of 3rd party equipment, you can just pull the upgrade out. Try that with some of the Mac upgrades! --alex

Jez:
    The memory controller, if you look close, has an extra address line coming out of it. It also has an (an?) another set of RAS and CAS lines for a second bank of memory. If you plug 256K chips in, you get 1Meg. If, however, you

plug in 1Meg chips, and run that extra address line to them (I KNEW that thing was there for a reason!), you can get 4 meg, thusly: 2 banks of 16 1Meg chips-->better known as 4 sets of 8 1Meg chips, or (ta-da!) 4 meg. As for our board, if you don't want to desolder, (not surprisingly), you cut the chips that are there out (ok, so it's 40 bucks down the drain, big deal.). You then socket the spaces, and plug our board in, and run three jumpers to the memory controller. It's not a big deal for anyone who's halfway decent w/ a soldering iron (I did the preliminary one myself, and I'm four thumbed, if you know what I mean), because you're not soldering anything delicate, like memory parts. That's why we recommend just cutting the chips out... You CAN desolder 'em, but the extra effort required to do it right just isn't cost effective. And besides, what if you make 1 chip just >>slightly<< flaky?? Nightmare time... Just cut 'em out and be done with it... --alex

Attached is an article from the Antic Online magazine on Compuserve.

dgc

**** Start of attached article ****
   Permission to reprint or excerpt is granted only if the following line appears at the top of the article:

   ANTIC PUBLISHING INC., COPYRIGHT 1985. REPRINTED BY PERMISSION.

   ANTIC'S LONDON REPORT:

   ST RULES BRITTANIA
   UK SOFTWARE AHEAD OF USA

by JAMES CAPPARELL, Publisher

(ANTIC just returned from London, represented there by Publisher and President James Capparell, and Marketing Director Gary Yost. Here's their report.--ANTIC ED)

9/8-This article is being written on a Pan Am flight returning to San Francisco from London. What did we learn overseas? Well, there's five pence to a shilling...the people are extremely nice and the enthusiasm for Atari is excellent. But the weather in London is awful and pubs close at 1l pm.

Our most exciting discovery was the extreme enthusiasm for the Atari ST we found at the Personal Computer World Show held September 4-8 at London's Olympia Hall. Over 50,000 people got their first opportunity to see the 520ST and the 130XE. This was the eighth show sponsored by Personal Computer World Magzine so far, and by all reports it was the most successful. The Atari booth was one of the largest and best attended at the show. In the UK and European market, the ST looks like a strong winner.

Suprisingly, our British cousins have a leg up on developers in the States with stunning ST systems software, business software and games all ready for market. Perhaps because they are used to programming for the Sinclair QL, a 68008 machine, they were primed and ready for the ST. The QL was a big disapointment with its small memory and slowness. So for Britons, the ST seems like the QL that never was. And the British are much more open to developing for a new, unproven machine than American companies are. Big Blue Mania has not set in, as the British think the IBM line is far too costly.

Atari Corp. was well represented with a large contingent from the states. Jack and Leonard Tramiel, Sig Hartmann, Sig Schreyer and Shiraz Shivji flew in from Sunnyvale. Additional support from Atari UK, (an excellent organization, I might add) came from Les Player, Robert Katz and Jon Dean. I was pleased to also see German, Swiss and French Atari representatives.

We found some excellent languages and software products you will soon see from the Antic Catalog or other publishers. These included accounting and small business packages, LANs and a possibility of UNIX. We saw several languages including UCSD and ISO Pascal code compilers (very professional, very fast), super-fast macro assembler-editors, Lattice C, Cambridge Lisp, MODULA II, FORTRAN 77, and CPM 2.2 emulation. (I bought UCSD Pascal back with me so watch for a review soon.)

For you telecom buffs, it's interesting to note that the first truly Hayes-compatible modem for the Atari was introduced at the show. It costs 399 pounds and contains six different protocols, including two for videotex graphics -- the one area in telecommunications where the English have a significant lead on us.

An animated game called Brattacas from Psygnosis Ltd. drew major crowds at the show. It had already been in development for the past two years on SAGE 68000 systems. So it was ready to be ported to the Atari ST and was brought to beta level just a few weeks ago. Brattacas features cover art by fantasy artist Roger Dean. Better than arcade quality color characters move in a sophisticated scenario where the 520ST's graphics capabilities are exploited more than in any

other program we've seen so far.

In an enclosed glass room was a 260ST with one megabyte of RAM. Basically, it was a 1040ST with a built-in floppy, but still a prototype. Alongside it, a 520ST with color monitor attached to a 10 megabyte hard disk was displaying pictures at blinding speed during the entire show.

As an interesting twist, an Israeli political cartoonist, Yakov Kirschen , (famous for his "Drybones" character in the Jerusalem Post) was featured in an front page article in the Sunday London Times. In the photograph, he was showing a 520ST interactive cartoon character which demonstrated how artificial intelligence can be applied to computers. His character can actually relate to

the user. More on this after we interview Kirschen tomorrow during his visit to our office in San Francisco.

Also upcoming is a story about all the Atari products at the show, not just what was shown at the Atari booth, including a Zoids game and a demo of Jeff Minter's psychedeliC Colourspace light synthesizer for the XL/XE and the 520ST. This does for color what the synthesizer did for sound, and gives you a light show on your micro.

On the 8-bit front, we found out that the official Atari UK 8-bit software catalog of over 600 titles contains 54 Antic Catalog products distributed by Software Express International, Antic's European distributor. Additionaly, Atari UK issued a press release during the second day of the show with a list of 10 formally "Atari-approved" titles. We're proud to announce that the Antic Catalog's Earth Views and Space Base are among these first ten titles.

Antic has signed a number of publishing agreements with UK authors. This means the Antic Catalog will soon be bringing you lots of ST packages including development languages, systems software, business and productivity packages, utilities and games.

I would say that anyone who still doesn't believe that Atari and the ST are for real -- isn't for real. It's a great product at a great price (750 pounds in the UK) and has a growing list of developers. We saw a list of 450 developers in the UK alone. The day after the show closed, UK ST Product Manager Bob Katz returned to his office at 9 a.m. and found eight checks for development systems that had arrived by courier from developers who were itching to get started.

We were introduced to many fine Atari friends during our stay and were pleased to discover that our Atari community is just as enthusastic and supportive in London and UK as in the United States.

Those of us who have long been so loyal and dedicated no longer have to feel embarassed about being Atari fans. We have the fastest machine at the best cost and a growing development network. Watch Antic for ongoing Atari news from the states and around the world.

I agree, but I don't understand why you're "not fond of the Amiga emulating
a PC and running MS-DOS". Seems to me that users would like to use the
same operating system at home as they do at work. So if the Amiga or the
520 ST ran Unix or MS-DOS, it would be a more attractive machine both for
serious home users as well as low priced commercial users.
     Industry is buying PC's in large quantities in order to automate.
If a microcomputer manufacturer wants a large customer base, he should
make his machine attractive to commercial & industrial users, not just
home users. An individual buys one computer, one or two disk drives,
one printer. A company buying equipment for use within its offices buys
hundreds of computers, hundreds of printers, peripherals, etc. I can't
picture a commercial company buying hundreds of 520 ST's no matter how
cost effective it may be, because it doesnt attempt to fit in with the
traditional office environment of MS-DOS, Unix, IBM-PC compatible software,
etc.
     Too bad, because if you had one at the office, maybe you wouldn't
have to buy a complete system for home - you could borrow some of the office
peripherals over the weekend.

Regarding the casette interface, I don't see how it can be done entirely in software. The casette output is an analog voltage whose magnitude depends on the volume control setting - you would need some hardware simply to convert it to a standard voltage level, say TTL.

The interface converts FSK (frequency shift keyed) audio tones to digital bits. The bits are asynchronous serial with a start bit, data bits, and a stop bit. Baud rate is 600, a ZERO is a 3995 Hz tone, a ONE is a 5327 Hz tone, the tone durations are equal. The output of the casette needs to be converted to TTL levels (0 or 5 volts for logic ONE or logic ZERO) before feeding to computer. (I may have the ONEs and ZEROes swapped, and may be off a few Hz, but the info is basically correct).

Don't be too sure the Atari folk are totally disdainful of the IBM-PC compatable world. TOS (or GEMDOS) used in the Atari is essentially a 68000 version of MS-DOS, and there are little things like using IBM key scan codes, an IBM-PC compatible disk file structure, etc. If you can write a software emulator for an IBM-PC which runs on the Amiga, you should be able to just as easily write one for the Atari ST, especially considering the above. Of course you could just put a 8086 or 80286 in a box on the side for that matter.

I'm not too sure what the folks at Atari have up their sleeve, but I doubt they've missed anything so obvious as the position the IBM-PC has in the market. Neither have the Commodore people.

This is my first attempt at a message into networkland, so hello to
everyone.

I'm interested in obtaining information on the "beefed-up" version of
the Haba 10Mb hard disk for the 520ST.   I want to buy an ATARI
development system, which would seem to merit the purchase of a hard
disk, but I do not want to fall into the "IBM-AT trap", where I would
not be able to leave the system on for more then eight hours at a time
and obtain a 40% disk failure in two months time.
  I had called Haba at the 818-989-5822 number but the person I spoke
with was somewhat less than informative. He was not even aware that
a heavy duty development version of the 10Mb hard disk was available.
Is he right?? I live in the Cambridge, Mass. area, and I would like
to know if there is someone/place to go for information on obtaining
the drive.   Thank you all....

                        Ted Bailey

The memory management unit on the ST is more of a memory controller. It handles refresh for up to 4 megs of memory organized as two banks. Even if you have different amounts of memory in the two banks it will configure it as one contiguous segment. The only memory management that it does that I know of is that certain areas of memory such as i/o space and and the first 1k of memory where the exception vectors are located are protected from writing when in user mode. Of course there could be undocumented features that we don't know about but then they could have easily made the text area of the operating system read only which I don't think is the case.

>If this is the case, does that mean that the 512K in the machine is
>really the CACHE for an external RAM disk?

You may not be far off the mark. Rumors indicate that atari already has in prototype form an expansion box with a 32bit graphics processor. The ST might in this case be used as an i/o processor for the keyboard, disk, etc. Using the 512k as a cache would be very useful in speeding up the effective access times of todays slow hard disks.

>I noticed that 1.33Mbytes/sec is about 10Mbit/sec, anybody know of an
>Ethernet to SCSI interface?

I know that this has been done. For example sequent has an ethernet controller off their scsi interface. I am very interested in this application. If somebody knows more about the atari interface and how it compares to SCSI please post it to net.micro.atari.

>'Presenting...' describes the BIOS vectors and the BDOS vectors, where is
>VDI? Is it a 'trap vector', a 'run-time library', or a 'link-time library'?

The vdi or gsx calls are done via traps. I believe it uses trap#2. That is why you have to allocate those silly arrays when you use vdi calls since that is how you pass parameters.

>Does VDI use the Graphics chip to do the painting, or does it 'bit bump'
>like the MAC?

The graphics processor is not documented very well(if at all) so the following is mere speculation. The graphics processor handles the generation of the video signals for both rgb and monochrome outputs. For monochrome output it uses a an internal crystal to generate the 70hz non-interlaced video. It also handles the 512 color palette for the rgb mode. The atari also has something called bit block transfer. There is a possibility that the graphics processor does this through a dma transfer. This is not an ordinary transfer since it involves non-contiguous sections of memory. A couple of things point to this. One try moving an open window on the desktop. You will notice that you cannot move it by single pixels in the horizontal direction but by small fixed increments implying word boundary limitations typical of dma operations. Also there are two screens one logical and one physical used for animation.

Line drawing is done in software though.

Alan:
    Still looks to be about 3 or 4 weeks away. We're changing the design so
that you don't have to cut all your chips out of the board. (Whew!) The
reaction we got to that idea was about the same reaction as to a large furry
animal meeting it's maker on your living room carpet... That is to say,
everyone (including us) hated it. But there appears to be a real nice way
around it, which will involve much less modification of your main PC board, as
well as allowing us to lower the price on a fully populated board... Will keep
you informed. --alex

To: Argonaut Sftwre, Jez San 72247,3661

Jez:
    At first, it was gonna plug into sockets for all the ram chips, which meant you were gonna have to cut them out and socket them. You can imagine how well that went over. The design now is to cut out 2 chips (1 from each bank) and socket those, so that you get the address lines, and some power and ground. Other lines will also run for power and ground, as well as the three new lines for RAS and CAS. You will not have to touch your 68000. (Goodness knows I be terrified to touch mine!). --alex The board plugs into those two sockets, and sits above and in back of the current ram...

A number of regional dept. stores (Abraham & Straus in NYC metro,
Woodward & Lothrop in DC, etc.) have a 'Computer Depot' department.
When I mentioned to someone in the DC store above that I had seen
a similar department in a different dept. store around NYC, I was
informed they were an independent operation which provided an 'instant'
computer department for such stores.

Oops, I blew it and added at least one misconception. I remembered the
mention of the 68010 as being in the machine area of the documentation, but
I was wrong. It was under GEMDOS, which is not specific to the ST. There
is no mention of the 68010 in the hardware section (Atari specific) in the
documentation and any speculations I made concerning that are foolishness.

The ATARI 600XL is a downgraded version of the 800XL. Both are
compatable with the old ATARI 400 and 800 series. Disk drives,
printers and other external devices are compatable, however the
16K memory in your 600XL will not effectively support a disk drive.
I remember that the 600XL does have memory upgrades available for it.
Finding one may prove to be a problem. I would try some of the
old retail store outlets such as Sears or La Belles. They may
have one on their discontinued shelves. I am not sure if the
ATARI 400/800 memory upgrades will be compatable but I kind of
doubt it. Another note about 400/800 to 600XL/800XL compatability;
some of the old software will not run on the XL series without
what is called a translater disk that simulates the old 400/800
operating systems on the 600XL/800XL.

Is it my imagination, or is 42nd St Photo selling the 520ST at
full price? They seem to be asking 999 for the version with color
monitor. I didn't think they ever sold anything at full price.
Has Tramiel found some magic way to bind sellers effectively to
list prices?

It seems to me that a major disadvantage of the ST is that the CPU
is in the keyboard, resulting in a myriad of cables plugged into your
keyboard.

A local user's group person hinted that it is easy to buy a keyboard and
plug it in so that you can have a detached keyboard. Anyone on the net
have any info on this?

Much traffic has been generated lately about possible availability
of Microware's OS-9 operating system on the Commodore Amiga and/or
the Atari ST. While I have looked over recent magazines for
references, it isn't clear to me what machines are currently
available running the 68K version of this O.S., or what software
is available for it. Note I am interested specifically in 68000
software for OS-9; I have seen many packages offered for the 6809
version. Ready availability of 'useful' software would likely
determine whether the porting efforts would be worthwhile.

Could someone with better background on this enlighten us as to
current vendors' offerings under OS-9/68K? Is there a readily-
accessible source for public domain routines? If traffic warrants,
I will summarize to the net. Thanks in advance.

Actually the ST can be currently expanded to 1Mb so maybe you should
call it a 512k expansion board. The memory controller can handle up
to 4Mb in two banks of 2 Mb so when 1 Mbit chips come out its likely
that the ST's can be upgraded to 4Mb with some hardware hacking.

I'd think that uuencode/uudecode would be fine. I've gotten IBM programs
that way, and we know there's a 'C' compiler for the Amiga. I'd also like
to suggest that where possible *sources* be posted, in plain text format.
They're much more useful than binaries...

I am not in favor of hype in advertising, but just to offer some
balance. I saw an interview with Jack Tramiel where he said he was
using existing facilities in taiwan to build the ST. He claimed
that labor accounted for only 2% of the cost to build the ST and
that 75% of the parts were made in the usa. The actual design of
the ST based on the schematics is by Atari, Japan.

-ravi

P.S. The atari ST and commodore amiga are not toys and in many ways
are superior to the "toys" some business types use.

<><><><><><><><>
I just got a new DS/DD SF314 drive for my ST. It works great, but I
can't figure out how to create a bootable DS/DD system disk. Just
formatting the disk double sided and copying the files off the single
sided system disk doesn't work, presumably because it needs the hidden
system files and/or boot tracks. Any ideas? (Alas, I don't have the
developer's package... sigh.)

Is the ST port really SASI? (Are we talking similar or are we talking
identical) In otherwords can I use a industry standard SASI controller
and Disk? This would be great.

This msg was meant to clear up a few misconceptions, although I think
it added at least one...:

> Subj: Notes on the Atari ST (about 60 lines)
>
> This is in response to an article by Rex Ballard which was a reply to a reply
> on Amiga memory management. Since the topic is the Atari ST I decided to post
...
> You also mentioned TOS, which is reportedly a version of CP/M-68K. According
> to the documentation I have, it is not. TOS is a variant of a Digital
> Research operating system called GEMDOS, which looks very much like a 68K
> implementation of MS-DOS (or PC-DOS if you prefer). Like MS-DOS, it has a

GEM (not GEMDOS) is NOT an operating system. It is an operating environment
which is run on top of an operating system. TOS (which may-or-may-not be
a variant of CPM-68k) is the operating system. It would look very much
like the IBM PC-DOS in its structure, as GEM was originally intended for
use on the IBM-PC. The GEM running on the ST IS the DR operating environ-
ment, not a variant thereof.

I think that covers it.....

The disk is accessed as any other disk except with more storage. One catch
though is that disks formatted double-sided cannot be read by a single
sided drive.

I am going to use an 800xl as an interim solution to a machine-control problem, and as an interim terminal. To do this, I need to know the details of the various interfaces to the 800XL. Thus, the following questions:

1. What are the pinouts, signals, and timings on the interfaces: what do the signals mean, when are they sourced and sunk, what are the drive capabilities of the outputs, and the drive requirements of the inputs?

2. Where should I look to find this information, if it's not directly available in my mailbox as a result of this request? :-)

3. What about software interfaces--calling sequences, parameters, preconditions and postconditions for the entry points? The meanings of 'peek'ing and 'poke'ing at the various data elements?

Any and all helpful information, either answers or pointers, will be appreciated, not only by me, but by everyone that I praise you to.

TIA, also.

A while ago I sent a msg to the net asking if anyone had any info
on hard disk interfaces for the Atari. So far I have had no answers.
I just had an idea, and so I have a more specific question:

   The ATR 8000 (by SWP) allows interfacing to off the shelf 5&1/4
   and 8 inch disks. Does it also allow interfacing to hard disks?
   If so, which interface? SCSI would be nice because there is a
   Bernoulli Box which uses SCSI.....

     Thanks for any info,
              -Richard Hartman
              max.hartman@ames-vmsb

P.S.: Does anyone know if SWP is still around & functioning?

Why don't you ask your dealer if you can post these programs (if
possible with sources) on "net.sources"? That way they would get
to more people and without the trouble of sending for them.

The latest issue of Byte does a very good job of describing the Commodore Amiga in detail. Has anything similar been done on the Atari 520 ST? If so will someone let me know.

1) Atari Technical Notes (exact title I am not sure about)
2) For telecommunitions use A.N.A.L.O.G.'s "Chameleon" program.
   For wordprocessing use Atari's Atariwriter + program (when available)
   For other uses, who knows. Atari is supposed to be bringing out an 80
   column b-w monitor, but it may have been cancelled. For the above items
   Chameleons works with horizontal scrolling, so no special monitor needed,
   color tv is what I use. Atariwriter + will require a color monitor (Teknika
TJ-22 monitor will work -- TJ-22 is what I remember model number to be, but
   not having literature with me, I may have letters wrong. It is a three way
   monitor, RGB, composite and separated colors.
3) Atari 1050 (stock). There are ways to double denisity this drive, and
   various DOS's, but I use stock with no problems.
4) DOS 2.5 from Atari. I have used DOS 2.0S and DOS 3 from Atari, but have
   converted everything to DOS 2.5. If you use DOS 3, run--do not walk--to
   your nearest Atari user group and get a copy of 2.5. It allows you to
   simply convert all DOS 3 files to DOS 2.5. DOS 2.5 can be single or enhanced
density (ala DOS 3) and is compatible with early Atari disc drives. (Ex-
   cept that they cannot access all files on a enhanced denisty disc. Some-
   how 2.5 squeezes more files in around the existing DOS 2 files. An 810
   drive will see the disc as a single density disk, a 1050 will see the
   same disc as enhanced density.) DOS 2 is directly compatible with DOS 2.5,
   although you might want to reload your files onto an enhanced density disc.
   One comment, if you use 3 or 4 1050 disc drives together, you do have to
   do a modification of dos.sys. It consists of POKE'ing 7 (3 drives) or 15

(4 drives) into a specific location--if I had access to my hardcopy files I would give you the POKE location, but alas I am at work now and naturally the files are at home. (Murphy corollary?)

5) I use A.N.A.L.O.G.'s Chameleon program to access Tektronix Unix system all the time. It works real well, it gives docs on termcap needed. If you are at Tek, we have the termcap already installed at C1. It allows you to do functions (i.e. mail, vi, talk, etc.) using the VT52XL (or VT52) emulation modes. (Chameleon allows emulation of 6 different terminals plus the imaginary VT52XL which is an enhanced VT52.)
6) I have never run into the compatibility problems, but I do not run games on my 800XL. I also have an 1200XL which I prefer, altho at the moment it is dead due to chip failure (I think). I do have translater discs that originally came out from Atari, altho I understand that they have some problems and there is a commercial translater disc out now that resolves the probems--except that it must be purchased. I use a BASIC version C cart which solves all of the built in BASIC problems, as well as Microsoft BASIC II. OSS puts out a OS XL chip/board--I am not sure which it is. It sells for $69-79 and cures all problems as it essentially is the 800 OS for the XL's.

Is anyone with access to Compuserve planning to
download the Chris Crawford assembly language

tutorial? If you are able to post it here, I am
interested in taking a look at it. According to
the new Antic, it is in 8 parts, the first of which
is now available.

Thanks for any help.

I hate to dampen the Amiga fire, but the Amiga is a doomed machine.
How can I say this before 1 Amiga is sold? Simple, this is history
repeating it self, all over again. Remember the Comodore C-64 and
the Atari 800? It was obvious to anybody, who seriously looked at
BOTH machines, that the 800 was a better computer. But the Atari
cost twice as much. Guess which one, really sold. Want more proof?
Looked what happened last December, Atari sells 1/2 million 800XLs
at 89.95 while C-64 sales down 90%, and most people thought C-64
sales down due to "soft market", how come Atari sold 1/2 million,
price/performance. Enough history here is today:

```
Amiga 256k 1 internal floppy    $1295.00 "better machine"
Atari ST-260 1 internal floppy  $ 499.00 "1/2 the price"
```

Need I say more ?

Atari 520 STs are available "off the shelf" in the Los Angeles area
as of July 30th.

It seems that Atari and its original distributers in the LA area had
a falling out over "qualified dealerships" and STs are winding up in
stores like Computerland instead of small dealerships.

Anyone have experience with :

1) U S Doubler for 1050 drive: reliability, ease of installation,
   will it work with DOS 2.5?

2) Homepak software: is the terminal emulation any good? Does it
   emulate any known terminal?

3) Omniview 80-column adapter: how well does it work, what does
it work with reliably?

Please reply by mail. Thanks in advance.

Also, what experience do people have with Deep Blue C? Twenty dollars for a C compiler seems too good to be true. I'm especially interested in the ability to separately compile modules, to link with relocatable libraries, and the generation of reasonably tight code. I'd really appreciate any comments.

*** REPLACE THIS LINE WITH YOUR MESSAGE ***

For those of who have not seen the August issue of ANTIC,
here is a list and breif description of the major chips in the
520ST

1 2H-2123 Proprietary graphics controller (40 pin IC)
2 MC68B50P   Serial controllers. One for the MIDI, One for keyboard
1 YM2149 F   General Insturments sound chip (3 voices 30hz-20khz)
1 3H-2199BB   Proprietary Memory Controller (MMU ?)
1 MC68000P8   8 mhz processor
1 36-2120BC   Proprietary Glue Chip (Timing for everybody)
1 MC68901P   Multifunctional Peripheral Controller (RS-232)
1 WD1772A-AH Western Digital Floppy Controller
1 3H-2130CC   Proprietary DMA Controller

It should be obvious from the number and size of the Custom chips
that this computer has been under development a lot longer than one
would think. Two years ?

As a Macintosh developer I am very interested in any possible portability
problems in converting from the Mac toolbox to GEM. I have been told by
several people that, although not exactly the same, they contain the same
fundamental concepts (i.e. event driven, same type of window actions, etc).
I would like to evaluate exactly the portability question by obtaining
a manual for GEM and any other related manuals. Unfortunately, after
talking to Atari, they only bundle the manuals with the software packet.
I think this is quite unfair and am unwilling to shell out $300 for said
packet of software. I don't even have a machine to run it on. I am
wondering if there are any other people out there who have this information
who would be willing to send me a copy (of course I will pay for costs)
or at the very least give me some helpful insight into how GEM works
from the programmers point of view.

>cost twice as much. Guess which one, really sold. Want more proof?

It was obvious to who? - most certainly to Atari owners it was. I had
seen an 800 before I bought my C64 and as far as I was concerned, the
only thing the 800 had over the C64 was Star Raiders. My C64 had
better sound, more memory to deal with and equal graphics (maybe not
in color flexibility.)

>Looked what happened last December, Atari sells 1/2 million 800XLs
>at 89.95 while C-64 sales down 90%, and most people thought C-64
>sales down due to "soft market", how come Atari sold 1/2 million,
>price/performance. Enough history here is today:

>Amiga 256k 1 internal floppy $1295.00 "better machine"
>Atari ST-260 1 internal floppy $ 499.00 "1/2 the price"

>Need I say more ?

Yes. I don't care much about last December. Atari desperately sold
out as many machines as it could. Jack Tramiel needed the instant cash
to fund the ST. I'm sure Atari didn't turn a real profit on those
machines. The ST-260 doesn't even exist and the regular ST is having
problems.

Amiga 512K, 1 880K internal floppy $1500
Atari 512K ST, 1 400(?)K floppy   ~ 700

And the Amiga at least has a Basic (Microsofts best effort to date -
Atari has expressed doubts as to whether they will ever market one),
true multi-tasking and much more color flexibility than the ST. It's
sound also beats the ST by a large margin and it is more easily
expandable (up to 8.5 Meg of Ram total). There are already LISP, LOGO,
Pascal, C compilers available for the Amiga - what has the ST got?

The ST will never be able to preform the same as the Amiga. I'm willing
to pay double to not be left in a hole in a year when I want to expand
my machine. I can't guarantee the Amiga will sell - that remains to be
seen. I don't believe anyone should judge it prematurely - you must see
it first. Put it next to an ST or a Macintosh, then re-read the machine's
specifications and decide if it is the machine for you and to grow with
you.

Eric

I guess IBM, Apple, AT&T and the rest should either produce $100
computers or get out of the market place... Come to think of it,
how will the ST520 succeed with the 800 out there?

Seriously, there is a simple counter-example in TI and Timex both of
whom undercut Atari and Commodore, but are no longer with us
How do you explain that?

Both the 520ST and the Amiga appeal to various market niches, and

I suspect that both will capture portions of each niche. The higher price (and probable profit margin) for the Amiga should mean it will require a smaller portion to remain viable while the ST520 will need a larger share. If the ST520 cannot get this share IT may go the way of TI and TIMEX.

Actually, I don't expect (and really hope) either computer to go belly up, at least not until the next generation of personal computers comes along. Even then, I expect that each model will be enhanced to remain competitive with the new technology.

September 1985 ANTIC Table of Contents
Theme: Power Programming

Page Article

11 STARTING OUT: SOUND EFFECTS LIBRARY
This tutorial introduces beginners to the Atari's SOUND command. Includes a BASIC program that demonstrates 17 Atari sound effects.

13 GAME OF THE MONTH: CRICKETS
This is a frogger style game that was written by Stan Ockers. He has written many of the better public domain games for Atari and this has appeared on some BBS.

16 ST FEVER HITS ENGLAND
Anticipation for the ST series runs high in the UK.

17 ST ANY WAY YOU WANT IT
A discussion of how to use the GEM control panel.

19 ST GALLERY
Some examples of the graphics possible in the 640x400 mode.

20 MAPPING THE 520ST

The first "legal" memory addresses.

22 MORE ST PRODUCTS COMING
A look at the hardware and software announced and being developed for the ST. It includes addresses of most of companies.

25 REVISION C CONVERTER
If you own an XL computer with the buggy Revision B BASIC, this program will allow you to modify it to version C and save it on disk.

27 TIC TOC FLIP
This short BASIC program is an eye-popping demonstration of the page flipping animation technique.

30 ATARI TIME MACHINE
This article teaches you how to harness the power of Atari's timer registers for your own programs.

33 MIRRORED DISPLAY LISTS
Learn how to use mirrored display lists--a powerful graphics programming technique that easily produces distinctive effects without tying up a great deal of memory.

36 ONE-PASS DISK COPY 130
Copy your disks in one quick pass using the full 128K memory of the 130XE. Features single read/multiple write and write to multiple drives. Perfect for disk librarians.

38 16-BIT SOUNDPOWER
Beef up your Atari music from BASIC. Learn how to program 16-bit dual-voice sound to get richly melodic 7 octave music.

40 8 QUEENS ACTION!
Lightning-fast ACTION! solution to "The Eight Queens Problem" from the April 1985 ANTIC. 92 chess solutions in 40 seconds.

42 PLOTTERS FOR YOUR ATARI
A discussion of the hardware and software that is available to allow you to get a hardcopy of your graphics in color.

45 HACKERS FOREVER!
A book review of three recent books on the subject: "Hackers" by Steven Levy, "Out of the Inner Circle" by cracker Bill Landreth and "Neuromancer" by William Gibson (Sci Fi)

48 SIG*ATARI'S GREATEST HITS!
A discussion of the best of the public domain software available on CompuServe in several different categories. It gives the file names and a short description of them.

51 SOFTWARE LIBRARY
The program listings for all the type-in programs in the magazine.

70 ASSEMBLY LANGUAGE: FINE SCROLLING WORLD, PART I
Learn how to fine scroll with all the speed and power of machine language. This is the start of a two part tutorial by Mark Andrews, author of "Atari Roots".

73 PRODUCT REVIEWS
HARDWARE: Star SR-10 Printer (Star Micronics)
SOFTWARE: Trivia Quest (Royal Software)
Bank Street Music Writer (Mindscape, Inc)
Kampfgruppe (SSI)
Computer Title Bout (Avalon Hill)

Battle of Shiloh (SSI)
Broadsides (SSI)
Alley Cat (Synapse Software)

BOOKS: Guidebook to Winning Adventures
Dr. Wacko's Atari Basic
Home Computer Wars

Comments: The theme of this issue is power programming and many of the articles were designed as tutorials to help you learn how to use them in your programs. Most also contain short programs or, at least, sample listings so you can add them to your program. The editorial page contains a reader survey to help ANTIC determine what it's readers want. Be sure to let them know what you want to see more or less of. ANTIC has added several new programs to their software catalog and I will be updating my copy and posting it sometime this month. Their catalog now has an index and is broken up by categories. It is easier to read than earlier versions. There is a full page ad by VIP Technologies for their VIP PROFESSIONAL for the ST series of computers. You can order it direct for $99.95. It will sell for $149.95 after Nov. 1.

For Phil and anyone else who is looking for the address for Haba Systems, the software house the is going to produce a lot of ST software, here it is:

Haba Systems
15154 Stagg St.
Van Nuys, Ca. 91405

(818)-901-8828

The current (September) issue of ANTIC has the address of several
companies that will be producing software for the ST computers.

Oh yeah. And why aren't there more Pterodactyls down by the pond?
> Remember the Comodore C-64 and the Atari 800? It was obvious to anybody,
> who seriously looked at BOTH machines, that the 800 was a better computer.
> But the Atari cost twice as much. Guess which one, really sold.
Precisely the point. There are a lot of Atari 800, Comode C-64, & RS COCO
owners out there who are ready to place their 8-bit nibble juggler over the
nearest waste basket, let go of it, and let it take any old world-line it
pleases just to get their hands on a machine with a 68k, an accessable bus, a
set of coproc chips to handle the hard mundanities, a flexible window/keyboard
environment to snuggle up to the soft stuff, and a choice of TV or hirez
monitor color graphics to keep track of what's goin' on. The only crock is

"only one internal disk drive".
> Want more proof?
I'll listen.
> Looked what happened last December, Atari sells 1/2 million 800XLs
> at 89.95 while C-64 sales down 90%, and most people thought C-64

> price/performance.
Because they are (until September 15th anyway) still the guys with the
closest approximation to the desired performance/price.
> Enough history here is today:
Ok, poke your bet, man. I'm going for the Amiga, and I've talked to a bunch
of others who see it that way, too.
>
> Amiga 256k 1 internal floppy $1295.00 "better machine"
> Atari ST-260 1 internal floppy $ 499.00 "1/2 the price"

No, just go buy yourself an att7300 next year when they're down to $3000.

So how do you explain the IBM (PC/XT/AT)?

Maybe IBM will buy Commodore, and put the IBM sticker on it & call them
entry-level workstations. Voila!

Mike Kersenbrock
Tektronix Software Development Products
Aloha, Oregon

P.S. - Note that if Atari sells twice as many 520ST's as Commodore sells
Amigas, then Commodore will still be the bigger company in terms of
revenues. Assuming margins are proportional, Commodore is still
the winner insofar as owners are concerned.

P.P.S.- The battle will probably won in terms of software, and just
how much momentum can be gotten "up front". Also, the Amiga is an
"open architecture machine" which allows Commodore and add-on builders
to make money for each other (like the IBM PC). Is the Atari 520ST
open? Note: the Mac isn't.

>> Amiga 256k 1 internal floppy $1295.00   "better machine"
>> Atari ST-260 1 internal floppy $ 499.00   "1/2 the price"
.
.
.
Just as the C-64/Atari/Apple][have a different market than the IBM PC-AT, the Amiga has a different market than the Atari ST. Comparing the Atari ST to the Amiga is like comparing a Timex to a PC-AT. I think that the Atari ST sounds like a fine machine, and a good value for the money, but it is just not in the same league as the Amiga. I am not trying to start any arguments, just pointing out that there are a variety of machines with a variety of capabilities, with a variety of prices, for a variety of people. Every machine has it's pros and cons. I hope that the Atari ST and the Amiga both do well. It is the MAC that will really suffer as a result of these two machines. As usual, Apple will be selling less machine for more money.

I'm interested! I've got a simple one-point perspective program that I ported from MegaMax C (for the macintosh) to DR C for the 520. I'll post it as soon as I get my modem back up...

So here's a vote for net.micro.ST.sources.

Just a small flame: when the Atari ST was finally announced, the Amiga
faction was making jibes about the failure to get the TOS ROM software
solid enough to ship. Now the Amiga arrives with great fanfare, and a
small diskette amusingly named 'Kickstart' containing... well... the
AmigaDOS code that was supposed to be in ROM? :-) :-)

Help Please! Does anyone have the U.S. mailing address or net address
of Douglas Crockford. He is, of course, the author of the world's
finest "Adventure" game: "Sir Gallahad and the Holy Grail", an APX
winner. Thank you in advance.

I think it would be much more interesting to get first
a newsgroup net.micro.ST. If there is enough interest in
this group, a second group net.sources.st should be established.

{ any line eaters still active? }

I'm trying to hook up a 5.25" floppy drive to my Atari 520ST. So far it
hasn't worked. Has anyone else had any luck?

The 520ST uses the WD1772 disk controller chip. The folling signals are
used by the 520ST:

DRIVE PIN	Signal
2,4,34	not used
8	Index/sector (drive output)
10	Drive 0 select
12	Drive 1 select
16	Motor on
18	Direction Select
20	Step

```
  22     Write Data
  24     Write Gate
  26     Track 00      (drive output)
  28     Write Protect (drive output)
  30     Read data     (drive output)
  32     Side one select
rest     ground
```

I hooked the drives (Teac 5.25" and Atari 3.5") together with a 34 line ribbon cable, and wired in the dirve 1 select line. All signals look okay, but it doesn't work. Also I removed the termiation resisters and tripled checked the jumpers. I was working with a Teac quad. density double sided drive. Any ideas?

Thanks,
Wayne Knapp

P.S. The reason why I want to do this is that 2 double sided 5.25" drives with power supply cost less than one Atari drive. I plan to have a switch that will let me switch in the 3.5" drive as drive zero or switch in a 5.25" drive.

According to the latest issue of COMPUTER ENTERTAINER newsletter, Atari is taking a very strange and disturbing stance on defective units. This can adversely effect distribution of the 520ST. I hope they change it fast! I quote from the article:

> "Atari has just taken the stance that they will acept NO returns from distributors and or retailers. Instead, they will offer 4% discount to the distributor/retailer which is supposed to cover any losses due to defective returns. As a result, unless a retailer feels they can move large quantities, they simply cannot take the risk involved as mark-up in the computer area is traditionally
